Standardized installation practises are followed except that a boiling-out compound softer and more lubricating than paraffin wax, is required, particularly at low temperatures. A suitable compound has been found by adding paraffin oil to wax in varying proportions depending upon the temperature at the point of splicing. The anticipated savings have been realized in the operation of the commercial units and the further expansion of the uses of this insulation is being studied. (A.I.E.E. paper No. 32-122)

## Some Phases of Electrical Testing in a Rubber Covered Wire Plant

By
C. W. Protzman[9]
W. M. Hill[9]

DEVELOPMENT of new machines and processes for the manufacture of rubber covered wire made possible "straight line" production methods, with the elimination of process stocks and storage. However, the advantages of this method of production were reduced by the fact that the standard water test applied to the finished wire did not lend itself to this method of production.

With this process a stock of wire must be kept in the test tanks for a minimum 12-hr period, and stored in racks for an additional drying period. This requires stocks of process material, and in addition, the water test equipment requires a relatively large area; also separate equipment is necessary for coiling the tested wire.

A combined testing and coiling machine therefore was developed which wound the wire in coils ready for shipment and simultaneously furnished an electrical insulation test of the dry or "spark" type. The "spark" test involves the impression of a relatively high a-c voltage upon the insulation of the wire under test, with its conductor grounded. The entrance of a defect into this high voltage zone permits a flashover which actuates control apparatus to give an audible and visual signal and to stop the passage of the wire.

The circuit consists fundamentally of a specially built low power transformer with a condenser in the high voltage circuit to boost the commercial frequency to several hundred cycles when this circuit is closed suddenly. The signal and control apparatus is connected in the low voltage circuit. The voltage is impressed on the wire by means of an electrode approximately 5 ft long through which the wire passes, and the defect is located accurately for patching or removal by means of a small fault locator or electrode which is placed beyond the testing electrode.

Results of comparative checks on a large quantity of wire over an extended period indicated that the "spark" test performed more consistently than did the comparable water test. It is apparent that wider application of this method may be made by the entire rubber covered wire industry. (A.I.E.E. paper No. 32-120)

## Use of Cables for Telephone Distribution Purposes

By
M. C. Rose[10]
H. A. Russell[10]

TELEPHONE CABLES containing large groups of insulated conductors in a common sheath have been developed rapidly since 1882; previous to that time all telephone distribution was by means of overhead wire plant. The present maximum sized cables in use contain 1,818 pairs of 26-gage conductors in a sheath having an outside diameter of $2^5/_7$ in. The increase in the amount of cable in plant during the past decade in certain metropolitan areas, such as Baltimore, Md., and Washington, D. C., has been over 100 per cent, and at the present time the value of the cable plant represents about 25 per cent of the total plant investment in these areas.

The type of cable distribution whether underground, aerial, attached to building walls, or located in buildings, depends generally upon the character of the area to be served and the station density. A complete system of records continuously maintained is an essential in the design of the distributing plant. The more important features of economical design include the gage requirements for transmission, the provision of facilities to care for existing business, and sufficient spare at the proper locations to care for reasonable expectations of growth.

The uses of telephone cable for distribution purposes in typical metropolitan areas, such as Baltimore and Washington, is outlined in this paper, including some historical background as to the development of cable and the part it takes in the present over-all plant investment. The division of metropolitan areas into central office areas and the various types of distribution are discussed. The engineering procedure followed in the design of cable distributing plant to provide economically a metallic cable circuit of satisfactory transmission quality for each subscriber's line to connect with the central office, involves the consideration of many factors. (A.I.E.E. paper No. 32-121)

## Safe Harbor Project

By
N. B. Higgins[13]

DELIVERY of power to Baltimore, Md., from the first unit of the Safe Harbor hydroelectric plant on the Susquehanna River, began December 7, 1931, 20 months and 7 days after active work was started on the project site—an outstanding achievement in the annals of hydroelectric construction. The drought that prevailed during the construction period and the absence of high floods were important contributary factors to the speed with which the work was executed. In an average year, the Safe Harbor plant will generate over 800,000,000 kwhr, resulting in an annual coal saving in excess of 500,000 tons.

In the lower Susquehanna basin between Columbia, Pa., and the Chesapeake Bay, there is a difference of elevation of about 227 ft. The initial development, now known as the Holtwood project, went into operation in 1910, and left available for future development a fall of about 100 ft below and 57 ft above Holtwood. The lower development, commonly known as the Conowingo project, was constructed and went into operation in 1928. The development of the head between Holtwood pool and Columbia, known as the Safe Harbor project, is the subject of this paper.

The various features in connection with this project are discussed in detail. These include the reservoir conditions, hydraulic structures, forebay, power house, and electrical features. A major problem in electrical design at Safe Harbor has been to provide a flexible layout which will permit the installation as required of equipment for generation, transformation, and transmission at 60 cycles 3-phase, and 25 cycles single-phase. The plant is of the most modern design throughout, incorporating many novel features. (A.I.E.E. paper No. 32-123)

## Safe Harbor-Westport 230-Kv Transmission Line

By
E. Hansson[13]

SAFE HARBOR development will have an ultimate capacity of 510,000 hp, a large portion of which will be available for Baltimore. During certain periods Baltimore will be dependent primarily upon this Safe Harbor power; therefore, reliability of transmission is of the utmost importance. The selection of the operating voltage was made only after a thorough investigation of the relative economic and reliability factors involved, the possibility of future interconnections, and system stability. Studies made in conjunction with the engineers of the Consolidated Gas Electric Light and Power Company of Baltimore covered a comparison of 2 23-kv circuits with 6 110-kv circuits. These studies also included investigation of such problems as terminal location, 2-point versus single-point supply, the use or omission of high voltage buses, and amount of synchronous condenser capacity required. An a-c calculating board was employed to check the results obtained by analytical methods.

---

[13] Pennsylvania Water & Power Company, Baltimore, Md.

The decision was made finally in favor of the higher voltage as offering lower cost, greater reliability, and greater possibilities for interconnection. Voltage regulation on the city network and control of short-circuit currents made power delivery to each side of the city advisable.

A brief description of the design of the Safe Harbor 230-kv transmission lines is presented in this paper. Attention is called to the separate routes of the 2 lines connecting the generating plant with the load center at Baltimore. The lines are the most heavily insulated so far constructed, and the ground wire protection has been applied according to the latest theory. Special effort has been made to reduce tower to ground resistances. Conductor tension has been kept low and armor rods are used at all suspension joints to guard against vibration troubles. The type of concrete anchors used lessens construction costs and facilitates erection of towers.

After comparing various designs, a 795,000-cir-mil A.C.S.R. conductor was chosen. Much has been said about the frailty of A.C.S.R. and about the precautions needed to protect it against damage. The Safe Harbor line was strung without any special safeguards, yet it stands completed with only 3 repair sleeves, and 2 of those could have been left off. (A.I.E.E paper No. 32M16)

## Reception and Distribution of Safe Harbor Energy in Baltimore

By
A. S. Loizeaux[15]

ENERGY from the Safe Harbor development was first received in Baltimore during December 1931, and at once took an important place in the energy supply of this city. Baltimore has both 25-cycle and 60-cycle loads, the maximum 25-cycle load recorded being 125,400 kw, the maximum 60-cycle load being 104,800 kw, and maximum simultaneous load on both frequencies being 188,200 kw. The 25-cycle frequency was originally chosen for industrial purposes and for the operation of rotary converters, although in recent years growth on this frequency has been held back. Shortly after completion of the Safe Harbor-Westport transmission line the frequency at Baltimore was changed from the former value of $62^1/_2$ cycles to 60 cycles, and the older frequency changers were shut down. One 30,000-kw frequency changer at Westport now takes care of all energy interchanged between these 2 systems. The characteristics and control of this frequency changer are described in the paper.

A bank of surge proof transformers of 126,000-kva capacity step down the Safe Harbor energy from 230 kv to 33 kv in a new outdoor substation. This 33-kv system ties into the 2 principal steam generating stations in Baltimore, and through them to the transmission system, chiefly of 13 kv, extending to Baltimore substations and surrounding territory. The main features of these transmission systems are described in the paper. (A.I.E.E. paper No. 32-126)

## Low Head Hydroelectric Developments

By
A. V. Karpov[14]

THE DESIGN of an up to date low head hydroelectric power plant requires a thorough understanding of the ideas and theories that have originated within the past few years in connection with such developments. The present paper is an attempt to review the latest work and to show some of the changes that have been made in the design of low head plants.

In the eastern part of the United States, and to a greater extent in Europe, power sites that could be developed economically by the use of conservative Francis-type turbine are diminishing rapidly. Many of the remaining low head sites can be developed only by the use of more economical methods; that is, by turbines of the propeller and, particularly, the Kaplan type. Kaplan turbines have been in commercial use only for the past few years, the units at the Safe Harbor plant being among the largest of this type. It is stated that the development of this type of turbine was accomplished entirely in Europe.

Various types of low head turbines are discussed in this paper, including the various theoretical and practical considerations which must be given each installation. Comparisons of European and American designs are given and future trends are indicated. It is stated that the runner blades and, in general, all parts of the runner which come in contact with flowing water in the Kaplan units at the Ryburg-Schworstadt plant, Germany, are machined and polished. In contrast to this the steel castings smoothed only by hand or by emory wheels at Safe Harbor probably represent a lack of proper machining equipment in the United States. The low setting of the center line of the runner at Safe Harbor, that is, 6 ft below normal tail-water elevation, probably is due partly to this deficiency. The paper indicates future trends in design. (A.I.E.E. paper No. 32M15)

## Safe Harbor Kaplan Turbines

By
L. M. Davis[16]
G. W. Spaulding[16]

ONE of the numerous features of more than usual interest at the Safe Harbor hydroelectric development is the application of the Kaplan type of automatically adjustable blade propeller turbine. This type of turbine is used in all 6 units of the initial installation, each unit rated at 42,500 hp under a rated head of 55 ft. Safe Harbor is the first installation in America of Kaplan type turbines of large capacity, although they have been used for low head developments in Europe since 1919.

Many new and interesting problems arose in connection with these Safe Harbor turbines requiring, as with any pioneering development of this magnitude, an unusual amount of experimental and engineering study involving not only the hydraulic and mechanical design of the plant but affecting the structural and electrical design as well. The absence on this continent of a hydraulic testing laboratory in which cavitation tests could be made resulted in the construction of such a laboratory at Holtwood, Pa., adjacent to the Holtwood hydroelectric plant.

In addition to describing the laboratory at Holtwood and the tests carried out there, the paper includes the reasons for installing Kaplan units at Safe Harbor, together with a description of these units. In the laboratory, particular attention was given to cavitation, the phenomena resulting when a vacuum is formed under the runner blade. Tests on a complete model of the Safe Harbor intake, scroll case, wheel setting, runner, and draft tube, were made to determine within very close limits the highest elevation at which the runner could be set without danger of serious cavitation, for the maximum turbine power desired.

After deciding upon the general design of tube, further studies were carried out along 3 lines: First, the determination of the most economical length of the horizontal section of the tube; second, the determination of the maximum upward turn of this horizontal leg which could be considered without sacrificing efficiency; and third, the determination of the proper area at the discharge end of the tube.

The test program has resulted in numerous improvements in operating performance, and savings in construction costs. Engineers of the 2 turbine manufacturers cooperated in jointly developing and manufacturing turbines of identical design wherein practically all replaceable parts are interchangeable.

The first 6 months of actual performance indicate that the prediction of the cavitation limits is reasonably close, although a considerably longer period will be necessary definitely to establish a close correlation between laboratory and field results. (A.I.E.E. paper No. 32-124)

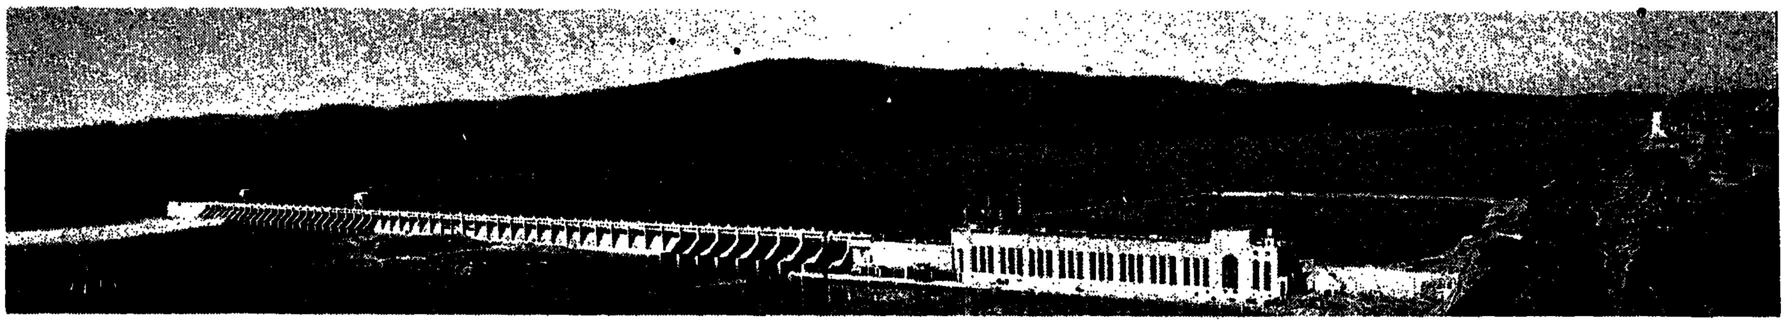
[16] Safe Harbor Water Power Corporation, Baltimore, Md.

# News
## Of Institute and Related Activities



Safe Harbor development on the Susquehanna River. This plant of the Safe Harbor Water Power Corporation will be visited during the coming Middle Eastern District meeting of the Institute in Baltimore, Md., October 10–13, 1932, and is the subject of several interesting papers to be presented. Six Kaplan type turbines, each rated 42,500 hp under a head of 55 ft, are installed in this plant and are the first large Kaplan type units to be installed in this country

# Baltimore Meeting Program Includes Interesting Features

CABLES both for power and for telephone use, and hydroelectric developments with particular reference to the Safe Harbor plant of the Safe Harbor Water Power Corporation on the Susquehanna River, are the outstanding features of the technical program arranged for the Institute's Middle Eastern District meeting to be held in Baltimore, Md., October 10–13, 1932, with headquarters in the Lord Baltimore Hotel. Inspection trips and entertainment features round out the program and assure a worth while meeting in this most interesting city.

### TECHNICAL SESSIONS

Four technical sessions will be held during the meeting. The first session is under the joint auspices of the A.I.E.E. and the National Research Council, with Dr. J. B. Whitehead presiding; it will deal with timely cable problems, namely, economics, thermal transients, and traveling wave voltages. Also, the paper describing the Columbia River 115-kv oil filled submarine cable installation is of particularly noteworthy interest.

The second session will present a group of papers on design, fabrication, test, and use of telephone cables, and should prove of wide interest. The third and fourth sessions will treat waterpower development with particular reference to the Safe Harbor plant, including transmission and utilization of the energy; they will also describe the research activities at the Holtwood hydraulic laboratory that culminated in the design of the turbine at Safe Harbor for operation at high efficiency under partial load and with variable head. The generating units at Safe Harbor, each rated at 42,500 hp, represent the first installation of Kaplan type turbines of large capacity in America.

The National Research Council committee on electrical insulation has arranged an informal session at which results of recent research in the field of dielectrics and insulation will be discussed.

### INSPECTION TRIPS

Among the inspection trips which have been arranged to various manufacturing plants, are those to the Bethlehem Steel Company's mills at Sparrows Point, the refinery and wire mill of the American Smelting and Refining Company, and the telephone cable plant of the Western Electric Company. A trip also will be made to the works and high voltage laboratory of the Locke Insulator Company where there will be a special demonstration involving 3,000-kv lightning impulses, and 1,000-kv 60-cycle waves. A special excursion will be made to the Safe Harbor hydroelectric plant where the Kaplan turbines, step-up substation, 230-kv river crossing, and other interesting details may be inspected.

### OTHER FEATURES

Baltimore has so much of general and historic interest to offer visitors that a sightseeing and entertainment program of unusual interest will be provided, including for the women a trip to Annapolis, the 300-yr old capital of Maryland which still retains much of the charm of Colonial days. Golf and tennis features also have been arranged in abundance. Full details of the entertainment features planned for the meeting will be given in the program folder now being prepared. Hotel registration cards will accompany this folder.

A meeting of the board of directors will be held on October 13, 1932, in connection with this meeting.

### COMMITTEES

The committees handling the various phases of the work in connection with the Baltimore District meeting are as follows:

**District Meeting**—W. B. Kouwenhoven, *chairman*, vice-president, Middle Eastern Dist.; G. S. Diehl, *secretary;* A. F. Bang, F. A. Connor, K. A. Hawley, C. N. Johnson, L. G. Smith, J. T. Walther, and G. L. Weller.

**General**—K. A. Hawley, *chairman;* J. Wells, *secretary;* J. R. Baker, A. F. Bang, G. S. Diehl, R. C. Faught, A. Hughes, W. B. Kouwenhoven, W. O. Peale, A. L. Penniman, Jr., and L. G. Smith.

**Papers**—A. F. Bang, *chairman;* J. R. Baker, W. B. Kouwenhoven, J. L. D. Speer, and J. B. Whitehead.

**Hotel and Registration**—L. G. Smith, *chairman;* J. M. Barry, C. A. Brunner, F. Hamburger, and J. L. Hildebrandt.

**Banquet and Entertainment**—W. O. Peale, *chairman;* G. S. Diehl, R. C. Faught, C. S. Fiske, D. G. Howard, R. H. Lang, A. J. Pates, and C. V. O. Terwilliger.

**Transportation and Inspection**—Adrian Hughes, *chairman;* E. W. Jahn, G. R. Page, A. Rusk, and I. B. Yeakle.

**Printing and Publicity**—A. L. Penniman, Jr., *chairman;* J. H. Davis, A. Hughes, R. L. McCoy, and J. Wells.

**Golf**—F. E. Ricketts, *chairman;* G. H. Gilbert and C. V. Woodward.

**Finance**—W. H. Meese, *chairman;* F. A. Allner, C. M. Cohn, J. H. Davis, and F. J. Irish.

**Ladies**—Mrs. J. B. Whitehead, *chairman;* Mrs. F. A. Allner, Mrs. D. G. Howard, Mrs. W. B. Kouwenhoven, Mrs. L. G. Smith, Mrs. C. V. O. Terwilliger, Mrs. R. L. Thomas, and Mrs. John Wells.

## Program

All technical sessions will be held in the Lord Baltimore Hotel and are scheduled on eastern standard time. Abstracts of all papers which at the time of this issue were definitely scheduled for presentation at the Baltimore District meeting are presented in this issue of ELECTRICAL ENGINEERING, p. 659–62.

### Monday, October 10

**9:00 a.m.—Registration**

**2:00 p.m.—Cables—A Joint Session of the A.I.E.E. and the National Research Council, Dr. J. B. Whitehead, *presiding***

THE COLUMBIA RIVER 115-KV OIL FILLED SUBMARINE CABLE, E. F. Pearson, Northwestern Electric Co., G. B. Shanklin, General Electric Co., W. R. Bullard, Electric Bond and Share Co., and S. B. Clark, Northwestern Electric Co.

THERMAL TRANSIENTS AND OIL DEMANDS IN CABLES, K. W. Miller, Utilities Research Commission and F. O. Wollaston, Commonwealth Edison Co.

VOLTAGE REGULATION OF CABLES USED FOR LOW VOLTAGE A-C DISTRIBUTION, H. R. Searing, The United Electric Light and Power Co. and The New York Edison Co., and E. R. Thomas, The United Electric Light and Power Co.

TRAVELING WAVE VOLTAGES IN CABLES, H. G. Brinton, F. H. Buller, and W. J. Rudge, Jr., General Electric Co.

### Tuesday, October 11

**9:30 a.m.—Telephone Cables—J. L. Dawson Speer, *presiding***

SOME PHASES OF ELECTRICAL TESTING IN A NEW RUBBER COVERED WIRE PLANT, C. W. Protzman and W. M. Hill, Western Electric Co., Inc.

PULP INSULATION FOR TELEPHONE CABLES, H. G. Walker, Western Electric Co., Inc., and L. S. Ford, Bell Telephone Laboratories, Inc.

USE OF CABLES FOR TELEPHONE DISTRIBUTION PURPOSES, M. C. Rose and H. A. Russell, The Chesapeake and Potomac Telephone Company of Baltimore City.

**Tuesday Afternoon**

A session of the committee on electrical insulation of the National Research Council, Dr. J. B. Whitehead, *chairman*, to be held at the school of engineering of The Johns Hopkins University. In this session the results of recent research in the field of dielectrics and insulation will be presented. Informal reports of progress will be presented by manufacturers, scientific societies, and governmental and university laboratories.

### Wednesday, October 12

**9:30 a.m.—Safe Harbor Development—A. F. Bang, *presiding***

*ECONOMIC ASPECTS OF WATER POWER, F. A. Allner, Pennsylvania Water and Power Co.

SAFE HARBOR PROJECT, N. B. Higgins, Pennsylvania Water and Power Co.

SAFE HARBOR-WESTPORT 230-KV TRANSMISSION LINE, E. Hansson, Pennsylvania Water and Power Co.

RECEPTION AND DISTRIBUTION OF SAFE HARBOR ENERGY IN BALTIMORE, A. S. Loizeaux, Consolidated Gas, Electric Light, and Power Company of Baltimore.

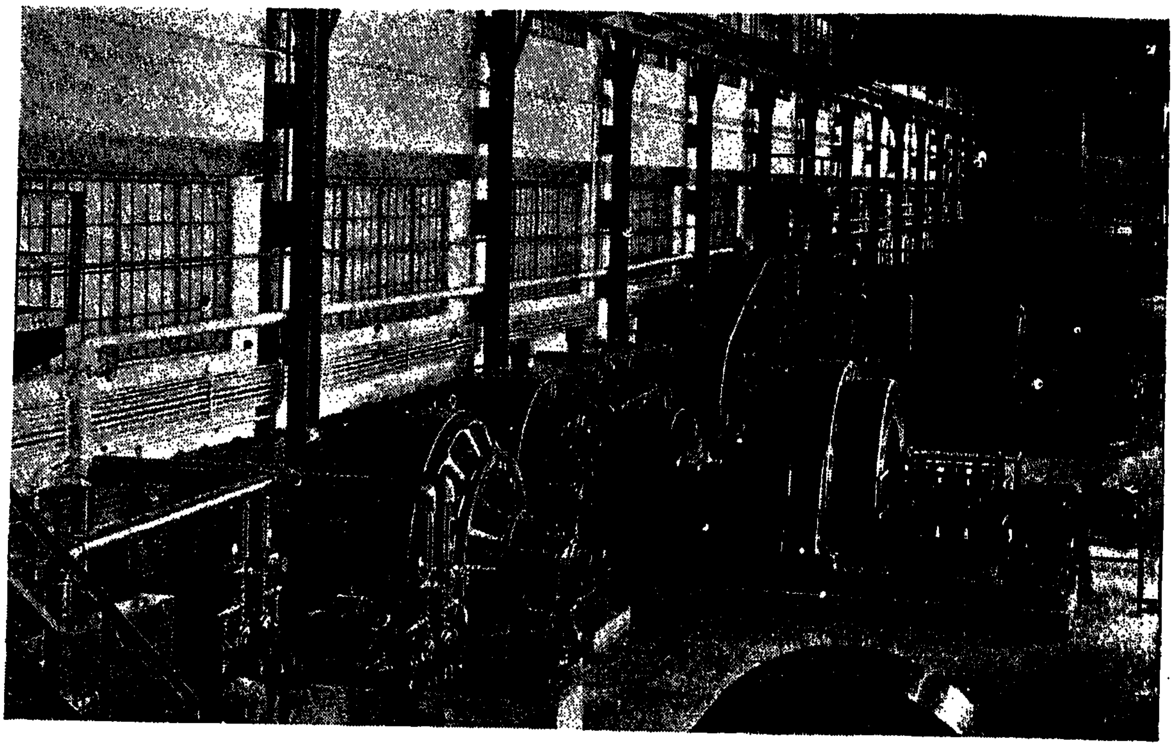
**2:00 p.m.—Safe Harbor Development—J. R. Baker, *presiding***

LOW HEAD HYDROELECTRIC DEVELOPMENTS, A. V. Karpov, Aluminum Company of America.

SAFE HARBOR KAPLAN TURBINES—DESIGN OF SETTING AND CAVITATION LIMIT AS DEVELOPED AT THE HOLTWOOD HYDRAULIC LABORATORY, L. M. Davis and G. W. Spaulding, Safe Harbor Water Power Corp.

**Wednesday Afternoon**

The meeting of the National Research Council, committee on electrical insulation, will be continued at the engineering school of The Johns Hopkins University.



**The Sparrows Point, Md., plant of the Bethlehem Steel Company may be inspected by those attending the coming Middle Eastern District meeting of the Institute, October 10–13, 1932. Above is shown a general view of the motor room of the 27- 24- 21-in. continuous skelp and sheet bar mill in the Sparrows Point plant**

### Thursday, October 13

Excursion to the Safe Harbor Plant

Note: Arrangements will be made for those desiring to return home promptly to connect with through trains at junction points.

### RULES ON PRESENTING AND DISCUSSING PAPERS

At the technical sessions papers will be presented in abstract, 10 minutes being allowed for each paper unless otherwise arranged, or the presiding officer meets with the authors preceding the session to arrange the order of presentation and allotment of time for papers and discussion.

Any member is free to discuss any paper when the meeting is thrown open for general discussion. Usually 5 minutes are allowed each discusser. When a member signifies a desire to discuss papers on other subjects or groups, he shall be permitted a 5-min. period for each subject or group.

It is preferable that a member who wishes to discuss a paper give his name beforehand to the presiding officer of the session at which the paper is to be presented. Copies of discussion prepared in advance should be left with the presiding officer. Each discusser is to step to the front of the room and announce, so that all may hear, his name and professional affiliations. Discussions at the technical sessions are not reported. To be considered for publication, discussions should be written and mailed to the A.I.E.E., Editorial Department, 33 West 39th Street, New York, N. Y., on or before Oct. 28, 1932.

**1931 Proceedings of International Conference Published.**—The full proceedings of the 1931 session of the International Conference on Large High Tension Electric Systems, held under the auspices of the International Electrotechnical Commission, has just been published (in French). They are in 3 bound volumes, 2,500 pages with 600 illustrations, are published by the International Conference, Avenue Marceau, 54, Paris, France, and cost 380 fr. Vol. 1 deals with generating and transforming equipment, vol. 2 with transmission lines, and vol. 3 with network operation, protection, and interconnection.

## Pacific Coast Convention Reports

The Pacific Coast convention of the Institute being held at Vancouver, B. C., August 30 to September 2, 1932, cannot, of course, be reported in this issue of ELECTRICAL ENGINEERING, but a general news story covering convention activities is scheduled for the October issue. It is hoped also that written discussion of the Pacific Coast convention papers will be mailed to the A.I.E.E. editorial department, 33 West 39th Street, New York, N. Y., in sufficient time and in sufficient quantity to warrant the presentation of a review of discussion in the October issue; written discussions are due in New York on or before Sept. 16, 1932.

The program of the Pacific Coast convention was announced in ELECTRICAL ENGINEERING for July 1932, p. 518–9, and abstracts of all papers then scheduled for presentation were given in ELECTRICAL ENGINEERING for August 1932, p. 583–6.

**Construction Reports for 1929.**—Census reports of construction figures, compiled from data gathered in the census of distribution for the year 1929, show the construction business of the contractors in various states for that year. These construction reports are now available for a number of states, and are being compiled for remaining states.

---

* These papers are under consideration for presentation at the Middle Eastern District meeting, but up to date of going to press have not been officially placed upon the program.

The bulletins are obtainable from the Superintendent of Documents, Government Printing Office, Washington, D. C., for a nominal cost.

## A.I.E.E. Directors Meet at Institute Headquarters

The regular meeting of the board of directors of the American Institute of Electrical Engineers was held at Institute headquarters, New York, N. Y., on Tuesday, August 2, 1932.

Present were: *President*—H. P. Charlesworth, New York, N. Y. *Past-presidents*—W. S. Lee, Charlotte, N. C.; C. E. Skinner, East Pittsburgh, Pa. *Vice-presidents*—K. A. Auty, Chicago, Ill.; W. E. Freeman, Lexington, Ky.; W. B. Kouwenhoven, Baltimore, Md.; E. B. Meyer, Newark, N. J. *Directors*—L. W. Chubb, East Pittsburgh, Pa.; A. B. Cooper, Toronto, Ont.; A. E. Knowlton, New York, N. Y.; G. A. Kositzky, Cleveland, Ohio; A. H. Lovell, Ann Arbor, Mich.; C. E. Stephens, New York, N. Y.; A. C. Stevens, Schenectady, N. Y.; R. H. Tapscott, and H. R. Woodrow, New York, N. Y. *National Treasurer*—W. I. Slichter, New York, N. Y. *Acting National Secretary*—H. H. Henline, New York, N. Y.

The minutes of the directors meeting of June 22, 1932, were approved.

A report of a meeting of the board of examiners held July 27, 1932, was presented and approved. Upon the recommendation of that board, the following actions were taken upon pending applications: one applicant was transferred to the grade of Fellow, 4 applicants were elected to the grade of Member and 19 were transferred to the grade of Member; 31 applicants were elected to the grade of Associate; 11 Students were enrolled.

Announcement was made of the committee appointments made by the president for the administrative year beginning August 1, 1932, and various representatives were appointed by the board. (The list of committees and representatives is given in this issue of ELECTRICAL ENGINEERING, p. 678-681.)

In accordance with the by-laws of the Edison Medal committee, the board confirmed appointments to the committee made by the president, as follows: D. C. Jackson, chairman for the year beginning August 1, 1932; Gano Dunn, S. P. Grace, and C. E. Stephens, for terms of 5 years each. Also, the board elected from its own membership to serve for terms of 2 years each: J. Allen Johnson, A. E. Knowlton, and R. H. Tapscott.

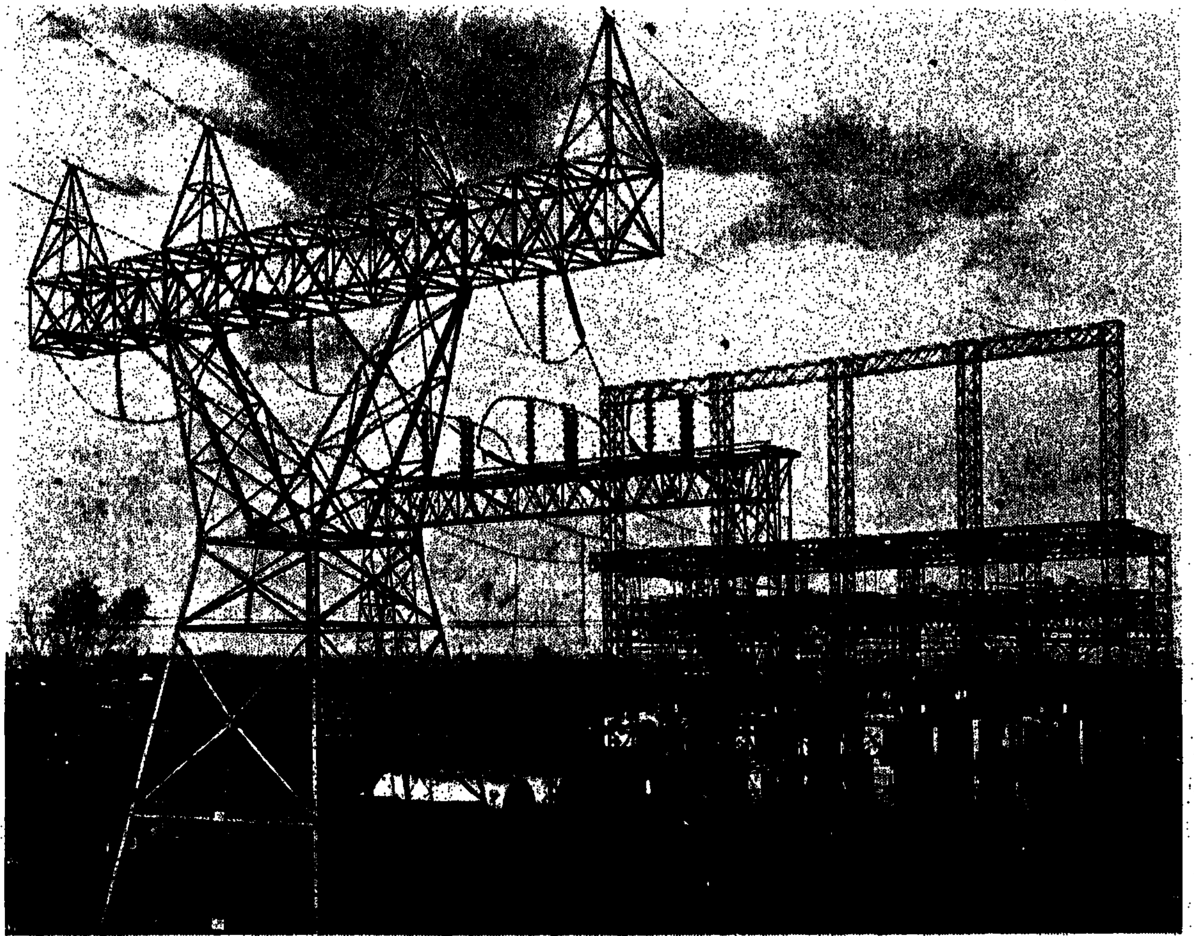
In accordance with the by-laws of the Lamme Medal committee, the board confirmed the following appointments by the president: P. L. Alger, H. B. Gear, and C. E. Skinner, for terms of 3 years each; C. E. Skinner, to serve as chairman for the year beginning August 1, 1932.

Local honorary secretaries were reappointed for the 2-yr term beginning August 1, 1932, as follows: V. J. F. Brain, for Australia; W. Elsdon-Dew, for Transvaal; A. S. Garfield, for France.

Various matters were discussed and referred to appropriate committees for consideration and recommendation.

Decision was made to hold the October meeting of the board of directors in Baltimore, Md., on October 13, 1932, during the Middle Eastern District meeting.

Other matters were discussed, reference to which may be found in this or future issues of ELECTRICAL ENGINEERING.



**Substation at the Baltimore, Md., end of the transmission line from the Safe Harbor plant on the Susquehanna River. Energy is transformed from 230 kv to 33 kv at this substation, and distributed at the latter voltage to other substations located at load centers. This substation may be visited during the Middle Eastern District meeting in Baltimore, Md., October 10–13**

## Engineering Board Appointed for R.F.C.

President Hoover (HM'29) has named the board of engineers which is to pass upon the engineering adequacy of projects for which applications for loans are made to the Reconstruction Finance Corporation. The board of 6 members consists of Charles D. Marx, *chairman;* John F. Coleman, John Lyle Harrington, John H. Gregory, Herbert G. Moulton, and Major-General Lytle Brown. The chairman of the board was selected by the president and the other members were selected from a list submitted by American Engineering Council.

Each major geographical division of the country is represented on the board, and consideration was given the experience of the members along the lines that most of the applications for loans are expected to cover. The chairman, Charles D. Marx, is professor emeritus of civil engineering at Leland Stanford University, Calif., and occupied the chair of civil engineering at that institution from its establishment in 1891 until his retirement in 1923. He has done considerable consulting work and has served as chairman of the state water commission of California. He is an honorary member and past-president of the American Society of Civil Engineers.

John F. Coleman, New Orleans, Ala., has been in consulting engineering practise in that city since 1900, specializing in river and port projects, land reclamation, and railroad and utility valuation. He at one time was principal assistant city engineer of New Orleans, and also is a past-president of the American Society of Civil Engineers.

John Lyle Harrington, Kansas City, Mo., is a member of the consulting engineering firm of Harrington & Cortelyou, Kansas City. Since his graduation from college in 1895, he has been active in bridge work, and for the past 25 years he has carried on a consulting and designing practise. He is a past-president of The American Society of Mechanical Engineers.

John H. Gregory, Baltimore, Md., is a consulting engineer and professor of sanitary engineering at Johns Hopkins University. He has been in sanitary engineering work since his graduation in 1895, first in Boston with the metropolitan sewerage commission and the metropolitan water board, and subsequently in private practise in New York and Baltimore.

Herbert G. Moulton, New York, N. Y., is a consulting engineer specializing in reports for banking interests on railroad and mining operations and finance. During the War he served with the war industries board, and from 1915 to 1920 was advisor to the Public Service Commission of New York on timbering in the New York subways.

Lytle Brown, chief of engineers, U.S. Army since 1929, is an *ex-officio* member of the board. He has had wide experience in government work both in the engineer corps and on the general staff of the Army, and is well known for his unusual executive ability.

## Prominent Civil Engineer Dies

Charles Warren Hunt, who was secretary of the American Society of Civil Engineers from 1895 to 1920, and then upon retirement from active service was elected secretary emeritus of that organization, died on July 23, 1932. He was born in New York, N. Y., in 1858, the son of an eminent lawyer, and in 1876 was graduated from a civil engineering course at New York University. In 1909 his alma mater conferred the honorary degree of doctor of laws upon him.

After a few years in varied engineering positions, Mr. Hunt was appointed assistant secretary and librarian of the A.S.C.E. in 1892, and in 1895 became national secretary of that organization. In this capacity he was untiring in his efforts to promote the good of the engineering profession, and many important accomplishments may be attributed to him.

**Lincoln Arc Welding Prize Award.**—A jury under the direction of Prof. E. E. Dreese (M'25) of Ohio State University, Columbus, awarded the prizes for papers in the second arc welding prize competition sponsored by The Lincoln Electric Company of Cleveland, Ohio. First prize of $7,500 was awarded to Lt.-Com. H. N. Wallin, U.S.N., and Lt. H. A. Schade, U.S.N., jointly for their paper "The Design and Construction of an Arc-Welded Naval Auxiliary Vessel." Second prize of $3,500 was awarded Maj. G. M. Barnes, U.S. Army, for his paper "Manufacture of Ordnance at Watertown Arsenal Revolutionized Through Arc Welding." The third prize of $1,500 was won by H. H. Tracy (A'26), of the Southern California Edison Company, Ltd., Los Angeles; the fourth prize of $750, by G. F. D. Wahl and H. E. Johns, Kiel, Germany; fifth prize of $500, by H. J. L. Bruff, Harrogate, England; and the sixth prize of $250, by W. H. Zorn, Wyandotte, Mich. Thirty-five additional prizes of $100 each were awarded to writers of papers showing the application of and saving possible by arc welding in every industry. Checks for the amounts of the 3 largest prizes were "written" on $^1/_8$ in. sheet steel; all information on the checks was arc welded, a submachine gun being used for cancellation.

## Fast Escalators Move London Subway Crowds

Increasingly heavy traffic in the London, England, subways recently has rendered inadequate the type of escalators previously used. Improvement plans of the London (Underground) Electric Railway Company, Ltd., required an escalator which would be capable not only of vertical rises higher than those possible with the present standard escalator, but also capable of higher speeds to permit a more rapid handling of passengers. This resulted in designing and building a new escalator suitable for a maximum vertical rise of 90 ft., capable of a speed of 180 ft. per min. (twice that of the old escalators), and computed to be capable of handling 16,000 persons per hr (or double the number of the old).

A sample machine first was erected and put into operation in the Otis Elevator Company's works at Harrison, N. J. After the usual tests it was inspected by the engineers of the London (Underground) Electric Railway Company, Ltd., and 51 of these new machines were ordered. They are to be installed at various subway stations in London, and for vertical rises of from 24 to 90 ft.

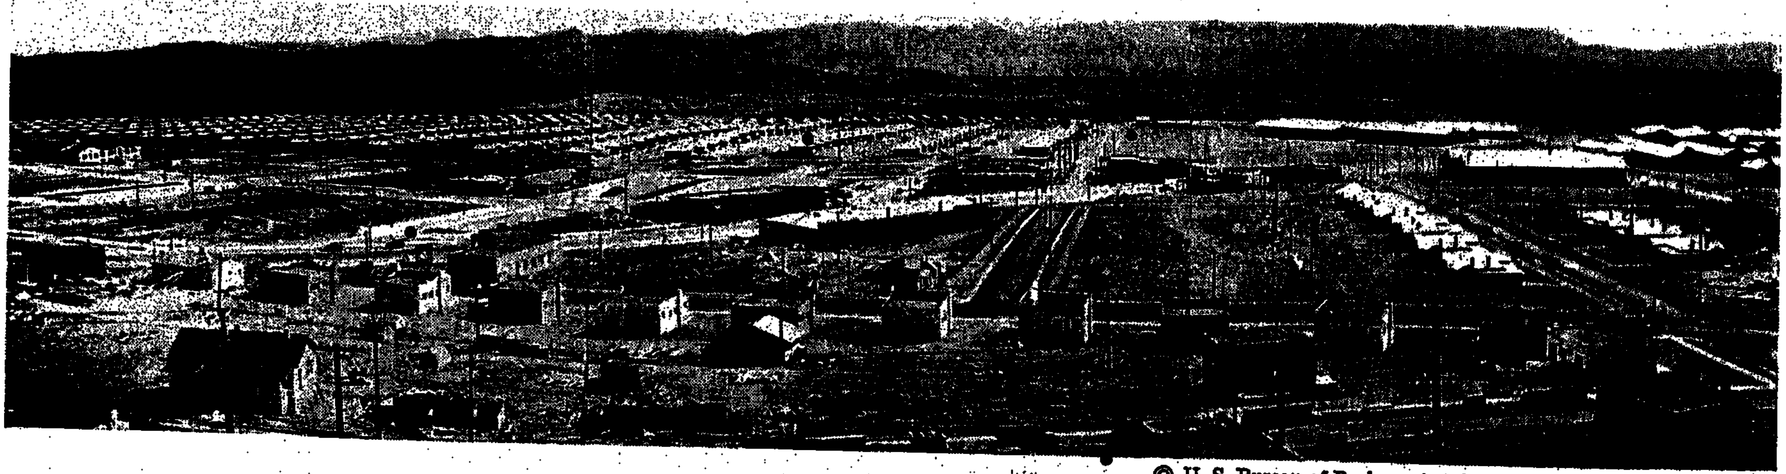
This new escalator already is proving a remarkable success. The public is showing no hesitancy in accommodating itself to the higher step-speed, and of course the quicker transportation is popular.

—From an article appearing in *Electric Traction and Bus Journal* for June 1932, p. 253.

**European Broadcasting Stations.**—Information on broadcasting conditions in European countries has been furnished by A. H. Morton (A'24) European manager of the Radio Corporation of America. He states that while European broadcasting is still several years behind that in America in programs and technique, in the opinion of most observers the European equipment is good and programs are improving. Russia has three stations of 100 kw each; Warsaw, Poland, one of 150 kw; France has one of 100 and one of 80. Scattered through Germany and Italy are 50-kw stations. Broadcasting is still largely under state influence which takes various forms; but in Europe interest in commercially sponsored programs is growing in the countries where it is not forbidden by regulation.

**Salary and Wage Reduction Survey Completed.**—A report which should do much to set at rest the vast amount of speculation as to the extent and severity of salary and wage cuts throughout the country during the present depression has been issued by the National Industrial Conference Board, Inc. The statistics presented are based upon unusually comprehensive and complete returns from 1,718 business concerns of every nature except agricultural, personal, and professional pursuits. Among the large number of significant facts revealed in this analysis is that the smaller business and industrial concerns have made more drastic reduction in salaries and wage scales during the present depression than have the larger concerns. Executive sala-

## Boulder City Emerges From the Status of a Construction Camp to a Complete City



© U. S. Bureau of Reclamation, Department of the Interior

Boulder City, Boulder Canyon project, Nev., organized to take care of the construction forces employed at Hoover Dam, is now the model construction city of the United States, and represents many of our national ideals. Comfortable homes have been built to house the workers and their families, dormitories and dining rooms have been constructed, schools, churches, and clubs completed, streets paved, and landscaping has been carried out on a large scale. A municipal organization has been set up under a city manager to assure adequate government for the population of over 3,000 employed persons and their families. Over 1,000 buildings have been completed, about 90 per cent of these being residences. Six Companies, Inc., owns the majority of these, although over 100 are owned by the government, and an approximately equal number by business permittees.

ries have taken the greatest reduction, with other salaries second, and wage rates the smallest. It also is shown that on the average, the companies making no reduction in wages have had the smallest decline in employment. Another significant fact brought out is that there was no general movement to reduce salaries and wages until the depression had gone into its second year. Also in contrast with earlier depressions, salary reductions have tended to precede wage adjustments.

# Letters to the Editor

**CONTRIBUTIONS** to these columns are invited from Institute members and subscribers. They should be concise and may deal with technical papers, articles published in previous issues, or other subjects of some general interest and professional importance. ELECTRICAL ENGINEERING will endeavor to publish as many letters as possible, but of necessity reserves the right to publish them in whole or in part, or to reject them entirely. **STATEMENTS** in these letters are expressly understood to be made by the writers; publication here in no wise constitutes endorsement or recognition by the American Institute of Electrical Engineers.

## Consumption, Production, Distribution

*To the Editor:*

What takes place to produce unemployment? First we will represent the circulation of money in the form of the diagram,

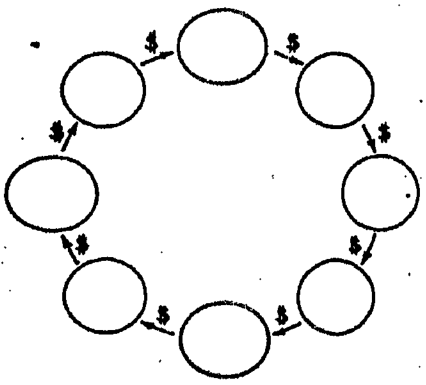


Fig. 1

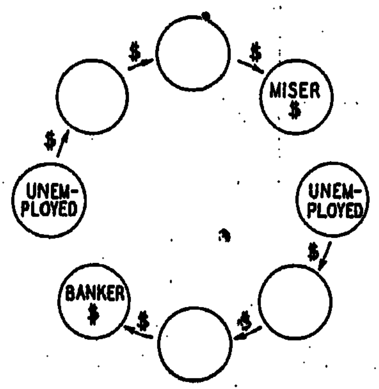

Fig. 2

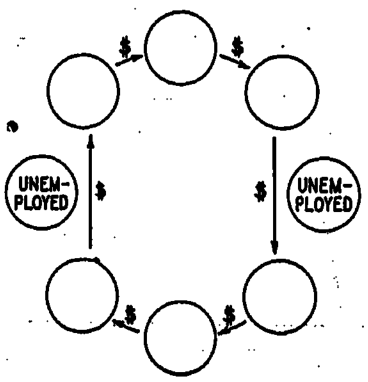

Fig. 3

Fig. 1. In this case the money is shown circulating from man to man in a perfectly organized society. Each man receives his turn at some of the money in return for some kind of goods or services.

According to the theories expressed by the progress report of the American Engineering Council ("The Relation of Consumption, Production, Distribution," ELECTRICAL ENGINEERING, June 1932, p. 373–9) there is some form of stoppage to this flow of money, which they describe by the expression that savings exceed investment. This hypothetical situation is shown by Fig. 2.

It seems entirely probable that there is some action of this kind, and that business is delayed by irregularities in the flow of money. But that this irregularity should be enough to cause a depression of the magnitude of the present seems incredible. What is more there is no evidence to support the theory. We cannot demonstrate that there was any greater irregularity in the flow of money in 1930 than in 1928. We cannot point to the men who were holding back enough money to give employment to 5,000,000 people.

A more reasonable theory of unemployment is shown by Fig. 3. This shows a normal circulation of money, but some men are left out. Instead of having in our community a population of 8, representing perhaps 8,000,000, we have but 6 and the other 2 are outside. There is no reason why a community of 6,000,000 should not get along indefinitely just as well as a community of 8,000,000. And there is no force in our economic system to make the 6,000,000 gather in the other 2,000,000, for each one can spend all of his income by exchanging within his group. No one has anything left to hire the other outsiders.

The problem of unemployment is to find some way to induce the circle to open up and take in the outsiders, for the mere fact that the outsiders are there will not induce any individual in the group to trade or hire them. At present the limiting factor appears to be a shortage of capital. Furnishing capital is a service as much as furnishing labor. The supply of capital is only enough to permit the group to be of its present size. Should more capital be saved, some of the capitalists would seek the outsiders in order to get a better and more profitable use for their capital.

Very truly yours,
A. W. FORBES (A'12)
(Forbes & Myers,
Worcester, Mass.)

**(Editor's Note: This letter is the third by Mr. Forbes discussing the economic problems covered in American Engineering Council's progress report.)**

*To the Editor:*

The special committee authorized by American Engineering Council in 1931 to study the relation between consumption, production, and distribution "interpreted its commission as being the selection and recommendation of such governmental, financial, and business policies as will maintain in the United States a standard of living that is high, broadly distributed, and free from severe fluctuations."

In attacking this problem the A.E.C. committee displayed excellent judgment in reducing the reputed number of factors bearing on the subject from 12 down to 8 and perhaps the most important of these 8 factors is that described in paragraph 5—"Controlling of money and credit to satisfy the needs of government, business, and individuals."

In publishing the full text of this A.E.C. committee progress report in the June 1932 issue of ELECTRICAL ENGINEERING, p. 373–9, the editors have rendered a time saving service by bracketing points that need emphasizing—for example that on p. 377 which will bear repeating:

"The stabilization of money is another possibility for large scale governmental and financial action. The seriousness of the lack of control of money value (or, the general price level as reckoned on a properly selected index) is beyond the power of words to express, because the world probably is in full movement on a secular decline with only minor short-lived upturns in prospect. It is important for governments and financiers to reconsider their attitudes on this question. A steadfast attempt to discover a safe and reliable means of controlling the value of money is required. Instead of being a question that is tabooed or ignored, it should be looked upon as the most important financial subject to which those in charge of the world's money can devote their energy and attention. There should be no rest until every possibility has been canvassed."

On p. 378 money and credit is involved in the A.E.C. committee's comments on public works, namely: "Herein lies an almost limitless field for the investment of private savings for public good that is socially profitable and economically stabilizing." In every relief bill offered, public works based on borrowed money have been discussed. Most of us believe that borrowed money should be repaid, and, as I write, the President's task of figuring out the rate of interest on borrowed money to be paid various parties, is the biggest point to be adjusted before the huge governmental relief bill receives his signature. Taxpayers are on the anxious seat and bankers who have the ready money (or will borrow some) must obviously figure risks as well as profits.

History records that Bellamy's book of the late eighties, "Looking Backward," inspired a hopefulness which was transferred into action by men in the electrical industry, and apparently history is about to repeat itself with hopeful plans transformed into action.

Here in Schenectady an electrical engineer from Pittsfield, Mass., recently outlined a plan involving the control of money and credit based on public works as a money standard which approached the subject in as business-like an engineering method as that employed by the A.E.C. committee in their recent progress report, and also inspired hope comparable with Bellamy's "Looking Backward."

Very truly yours,
H. W. TURNER (A'03)
(18 Troy Place, Schenectady,
N. Y.)

## Has Man Benefited by Engineering Progress?

*To the Editor:*

It seems to me that the Engineering Foundation's question "Has Man Benefited by Engineering Progress?" at once asks a question and answers it since "progress" applies only to a beneficial course of events.

An entirely different question would be "Has Man Benefited by Engineering Activity?" This last question allows inclusion of the development of war machinery and hence its answer calls for a critical and exceedingly comprehensive scrutiny of our present civilization.

Very truly yours,
P. K. SEYLER (A'26)
(Mountain States Tel. & Tel. Co., Denver, Colo.)

## Magnet Steels and Permanent Magnets

*To the Editor:*

Under the title of "Magnet Steels and Permanent Magnets" an article was published by K. L. Scott in the May 1932 issue of ELECTRICAL ENGINEERING, p. 320–3. I should like to make some remarks about this subject, explaining theoretically the experimental data of the work of Scott. Scott measures the induction $B_{rem}$ in the middle of rectilinear bar magnets of different steels, lengths $L$ and cross-sections $A$, and finds that $\frac{B_{rem}}{B_r}$ is only a function of $\frac{L}{D}\sqrt{\frac{H_c}{B_r}}$, where $B_r$ = remanence in closed circuit, $H_c$ = coercive force, $L$ and $D$ = equivalent diameter. Thus:

$$\frac{B_{rem}}{B_r} = \mathrm{f}\left(\frac{L}{D}\sqrt{\frac{H_c}{B_r}}\right) \qquad (1)$$

The form of this function is given in Fig. 2 of the article by Scott, which figure we reproduce here as Fig. 1.

Scott first tried to plot against $\frac{L}{D}\sqrt{H_c}$ but found it preferable to plot against $\frac{L}{D}\sqrt{\frac{H_c}{B_r}}$. We will show that the last method of plotting is the one to be theoretically expected.

The demagnetizing coefficient $N$ of a rectilinear bar which is not too short compared to its cross-section is given by:

$$N = 4\pi\beta^2\left(\log\frac{2}{\beta} - 1\right) \qquad (2)$$

where $\beta = \frac{D}{L}$ (this formula is valid exactly for an ellipsoid and for $\beta$ small).

$N$ being known for a special bar, we find the remanence $B_{rem}$ in the middle of the bar, as Fig. 2 shows, as the intersection point $P$ of the line $S$ and the demagnetization curve, if $\tan\alpha = \frac{H}{B} = \frac{N}{4\pi}$ (divided by $4\pi$ because we plot $B = 4\pi\mathcal{J} + H$ instead of $\mathcal{J}$, which is the intensity of induced magnetization).

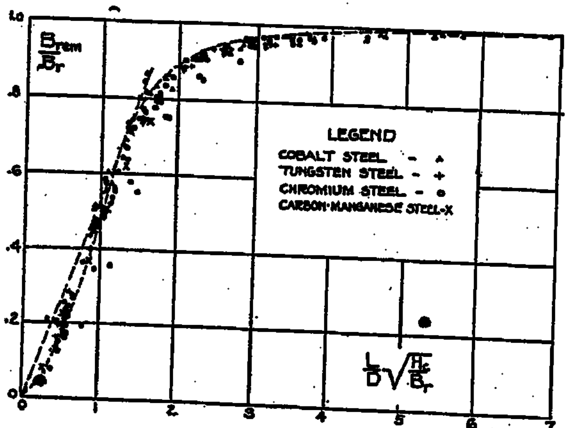

Fig. 1

Now experiments of R. L. Sandford (Bureau of Standards scientific paper No. 567 published in 1927) show that the demagnetization curves of all steels have nearly the same shape. If we therefore transform Fig. 2 into Fig. 3 by introducing the variables $\frac{B}{B_r}$ and $\frac{H}{H_c}$ instead of $B$ and $H$, respectively, the demagnetization curves of different steels fall on the same curve. In Fig. 3 we draw the line $S$ making the angle $\alpha'$ with the ordinates:

$$\tan\alpha' = \frac{H/H_c}{B/B_r} = \frac{H}{B} \times \frac{B_r}{H_c} = \frac{N}{4\pi} \times \frac{B_r}{H_c}$$

The point $P$ gives the value of $\frac{B_{rem}}{B_r}$ in the middle of the bar and as the demagnetization curve of Fig. 3 is valid for all steels, the value of $\frac{B_{rem}}{B_r}$ is only a function of $\alpha'$, that is, of $\frac{N}{4\pi} \times \frac{B_r}{H_c}$.

Thus:

$$\frac{B_{rem}}{B_r} = \varphi\left(\frac{N}{4\pi}\frac{B_r}{H_c}\right) = \varphi\left[\beta^2\left(\log\frac{2}{\beta} - 1\right)\frac{B_r}{H_c}\right]$$

In first approximation we neglect the variation of $\left(\log\frac{2}{\beta} - 1\right)$ so that we write:

$$\frac{B_{rem}}{B_r} = \varphi\left(A\beta^2\frac{B_r}{H_c}\right) = \varphi\left(A\frac{D^2}{L^2}\frac{B_r}{H_c}\right) = \mathrm{f}\left(\frac{L}{D}\sqrt{\frac{H_c}{B_r}}\right)$$

$\frac{B_{rem}}{B_r}$ is thus a single-valued function of $\frac{L}{D}\sqrt{\frac{H_c}{B_r}}$ as long as $\left(\log\frac{2}{\beta} - 1\right)$ may be considered as constant, and for values of $\beta$ not too large, because for large $\beta$, eq. 2 does not hold.

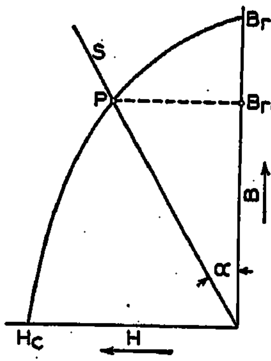

Fig. 2

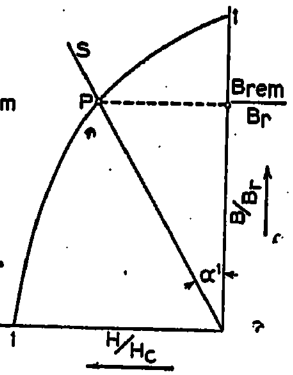

Fig. 3

As shown experimentally by Scott, the line in Fig. 1 through the origin and tangent to the curve has its point of tangency in the point corresponding to the point of maximum economy on the demagnetization curve (i. e., the point where $B \times H$ is at its maximum).

To show this and to calculate the function $\mathrm{f}\left(\frac{L}{D}\sqrt{\frac{H_c}{B_r}}\right)$, that is, to calculate the curve of Fig. 1 we must make an assumption regarding the shape of the demagnetization curve. I found good agreement with experiment (see W. Elenbaas, Physica, v. 9, 1930, p. 273) by taking the demagnetization curve as a quadrant of an ellipse. Therefore we write the equation of the demagnetization curve as:

$$\frac{H^2}{H_c^2} + \frac{B^2}{B_r^2} = 1 \qquad (3)$$

We find $B_{rem}$ as the intersection point of this ellipse with the line $S$ (Fig. 2). The equation of $S$ is:

$$\frac{H}{B} = \frac{N}{4\pi} = \beta^2\left(\log\frac{2}{\beta} - 1\right)$$

In first approximation we regard $\left(\log\frac{2}{\beta} - 1\right)$ as constant.

Thus:

$$\frac{H}{B} = \beta^2 A \qquad (4)$$

Eq. 3 and eq. 4 give:

$$B^2_{rem} = \frac{1}{\frac{A^2\beta^4}{H_c^2} + \frac{1}{B_r^2}}$$

$$\frac{B^2_{rem}}{B_r^2} = \frac{x^4}{A^2 + x^4} \text{ if we take } x = \frac{L}{D}\sqrt{\frac{H_c}{B_r}}.$$

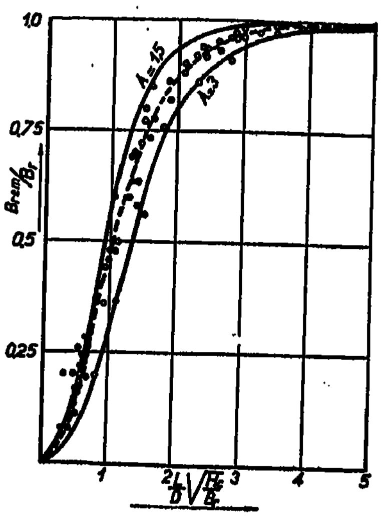

Fig. 4

Here again we find that $\frac{B_{rem}}{B_r}$ is only a function of $x$ and for the form of that function we find:

$$\frac{B_{rem}}{B_r} = \frac{x^2}{\sqrt{A^2 + x^4}}$$

Indeed this is a function similar to the curve of Fig. 1. In Fig. 4 we draw this function for 2 values of $A$, namely $A = 1^1/_2$ and $A = 3$, these being about the extreme values of $A$ in the experiments of Scott. The experimental points (a large number of the points of Scott are plotted in Fig. 4) fall satisfactorily between these 2 curves, except some points at low values of $x$. This is probably due to the fact that $\beta$ for these bars was so great, that eq. 2 did not hold (the greatest value of $\beta$ used by Scott was about $\frac{1}{5}$).

We find the point of tangency of the curve $\frac{B_{rem}}{B_r} = \frac{x^2}{\sqrt{A^2 + x^4}}$ with the line through the origin by making $\frac{B_{rem}}{xB_r} = \frac{x}{\sqrt{A^2 + x^4}}$ a maximum.

This gives $x = \sqrt{A}$
and therefore

$$\frac{B_{rem}}{B_r} = \frac{A}{\sqrt{2A^2}} = {}^1/_2\sqrt{2}$$

and in the case of an ellipse this corresponds indeed to the point of the demagnetization curve, where $B \times H$ is a maximum. The value ${}^1/_2\sqrt{2} = 0.7$ is in good agreement with the experimental value derived from the curve of Fig. 1, namely 0.65.

In this way it is possible to interpret fully the curve as found by Scott.

Very truly yours,
W. ELENBAAS
(Natuurkundig Laboratorium der N. V. Philips' Gloeilampenfabrieken, Eindhoven, Holland)

## Savings and Investment

*To the Editor:*

Mr. Forbes in his letter printed in the July 1932 issue of ELECTRICAL ENGINEERING, p. 527, regarding the American Engineering Council's progress report on consumption, production, and distribution, apparently put his finger on the sore spot without knowing it.

Referring to his illustration, suppose Mr. Smith keeps the $3, saves it. Mr. Brown keeps the hat. Brown may be the owner of the hat factory, Smith his employee. Anyhow, Brown has goods for sale, Smith is a prospective consumer, who has earned $3. No business is done, and we have "depression." Now if Smith's saving is invested, it goes to work, is paid to some one for building "capital goods," and a second consumer has the $3 and can buy the hat. The important thing is obviously movement, not a static equation showing the status of any particular $3 at any particular instant. The time element must be introduced.

The difference between savings and investment in the report is crucial; and the integration of these items over a time period (or else the rate with respect to time) is implied. It simply means finding the spot where the system is clogged. The volume of trade is forced to decelerate by diversion of purchasing power into the reservoir of hoarded wealth.

Where this hoarded wealth may be found has been disclosed by much material recently published. Another way of saying this is that there was a contraction of currency and credit. This did occur in 1929, contrary to Mr. Forbes, and the process has continued since then. The details involve an insight into our banking and credit structure, which is beyond the scope of this letter.

Very truly yours,
C. T. BUTTON (A'26)
(1133 Chamber of Commerce Bldg., Cincinnati, Ohio)

## Young Engineers Must Plan for the Future

*To the Editor:*

For a number of years I have been endeavoring to interest the most promising among our electrical engineering seniors and graduate students in thinking of our profession 10 to 20 years ahead of their time. It usually takes that long for a natural leader to reach a position in which he can actually lead a considerable group of workers. I always wanted such men to get at least a general idea of the directions in which our art and industry were moving at the time, so as to acquire the necessary mental equipment in the meantime. In 1905 I talked to them of huge transmission lines and of the necessity of understanding how to compute them both electrically and mechanically. About 1910 we had a chosen group struggling with transient phenomena and with plotting of electric and magnetic fields. In 1915 I used to annoy my graduate students by incessantly talking about electrons and about the important rôle they were going to play in electrical engineering. Then came the Heaviside calculus, power plant stability, thermionics, and what not.

For years this country has been handicapped in the development of electrical apparatus and in understanding some operating troubles by the false belief (natural in a pioneer country with only 2 political parties) that physicists, chemists, and mathematicians discover and investigate fundamental laws upon which the art of the engineer is based, and we engineers merely apply these laws and data to our problems. The Germans have developed a much more practical and flexible hierarchy of pure scientists, applied scientists, theoretical engineers, and practical engineers, with almost imperceptible gradations among them. The result has been that in Germany an operating trouble can be handed down (or perhaps up) from a practical engineer to a theoretical engineer; from the latter, in a modified form, to an applied scientist, and sometimes in the form of a general problem even to a pure scientist. With us, until a few years ago, if an operating engineer had trouble with some oil or paint he had to lay his story before a professor of chemistry who was liable to talk to him in terms of hydroxi-derivatives of phenanthraquinone, leaving the operating man exactly where he was before. It was partly this unsatisfactory situation which finally led to the formation of large research departments in our leading manufacturing and operating organizations. Nevertheless, there are still numerous gaps in many places. We need several types of middlemen between the pure sciences and the engineering art, and we need them urgently. Probably such intermediate men are also needed in economics and psychology, but this is another story for some one else to discuss.

It is with this idea in mind, namely, to increase the number of young theoretical engineers and applied scientists in this country, that I now urge intelligent students and former students to look forward not to an immediate job (or absence of one, as the case may be), but to a time when our industry shall demand an intelligent judgment about the group theory and restricted relativity in mathematics, theoretical spectroscopy and wave mechanics in physics, and an interpretation of the molecular structure and chemical reactions in terms of the quantum theory. All this may sound far fetched, but I remember the time when only a few chosen ones could handle alternating currents in terms of ordinary trigonometry, and when a d-c network computed by Kirchhoff's laws was sometimes checked on a small model, "just to be sure."

It is an ill wind that blows nobody good, and in these days of adversity and depression an ambitious young engineer with scientific leanings can do no better than to study the fundamental sciences and thus prepare himself for a place of middleman and interpreter in some specific problem of the industry of the future. The general tendency undoubtedly will be in the direction of more reliance on pure sciences, more accurate predetermination of performance of apparatus, and a rational analysis of troubles. No matter in which suitable branch of mathematics, physics, chemistry, or mechanics he decides to become an expert, he will be working toward ultimately becoming "geared" to the industry in an organic way, whereas one who shall place his reliance mainly upon good health, pleasing sociable personality, and a general idea of what a shunt wound d-c machine is, may later find himself in a long line of applicants with similar qualifications, all waiting for the same 15-dollar-a-week job. With the dawning socialization of the industries, the days of the glib-tongued salesman and prosperity manager are about over, and the truly scientific engineer will be soon coming into his own.

This letter is not the place to indicate specifically which topics I consider to be of importance in the future. The very process of finding fruitful paths of pioneering is an important part of the proposed studies, as well as a test of one's fitness for future leadership. Whatever subject one undertakes to master must be organically (although perhaps yet in a hidden way) connected with the present progress of the art, and not merely join it at some distant future. Anyone who would take the trouble of going over the Institute TRANSACTIONS, say for the last 10 years, keeping the forthcoming trends in view, will find any number of inspiring hints and clues. A similar study of the leading European periodicals devoted to electrical engineering should be the next step. Then, having decided to follow, say, some features of the science of electronics, the best American journals of physics should be gone over, and finally a detailed program of study arrived at. After this, it is merely a matter of finding suitable books and perhaps forming a connection with an experienced specialist for guidance and advice.

Very truly yours,
VLADIMIR KARAPETOFF (F'12)
(Cornell University, Ithaca, N. Y.)

## Suggested Changes in Dielectric Nomenclature

*To the Editor:*

I note with interest the increasing effort on your part to make our monthly publication a direct expression of the profession.

I am particularly interested in your publication of timely letters addressed to the Editor. I read with much interest a letter by Hubert H. Race (A'24) suggesting changes in dielectric nomenclature (see ELECTRICAL ENGINEERING for May 1932, p. 354–5). I approve Mr. Race's suggestions and believe there are many instances in which an improved nomenclature would make for clarity and convenience of expression in the electrical engineering art.

I have in mind a particular instance where I believe an improved nomenclature and the adoption of the name for a unit would be of advantage. I have in mind the unit of electric field intensity or voltage distribution per unit of length. This unit is now customarily expressed as volts per foot, or volts per inch, or volts per centimeter. I believe a single name for this unit, preferably called after some distinguished pioneer in this art, to be a desideratum.

I, therefore, take the liberty of proposing that the c.g.s. electrostatic unit of electric field intensity be called the "Franklin."

Very truly yours,
WM. W. FRASER (M'27)
(6 East 45th Street, New York, N. Y.)

## Patents on Arc Welding Generators

*To the Editor:*

We refer to p. 527, July 1932 issue of ELECTRICAL ENGINEERING, "Letters to the Editor," entitled "Eliminating Transients in a D-C Welding Generator" and more definitely with regard to the public assertion that J. Bethenod now has a patent on this double wound reactor for controlling the arc in a welding generator. We would like to have this letter published.

The writer was granted U.S. Patent No. 1,549,874, August 18, 1925, on this scheme. The scheme was invented and improved to practise sometime previously and if the patent laws of France were similar to the laws of the United States, Mr. Bethenod would not have obtained any patent on this.

In deference to the insinuation against the other 2 leading companies in arc welding, both of these are licensed under our patent and are probably, accordingly, interested in Bethenod's later development because in this country the man who does it first obtains the patent, and if it has been published, patented, described, or used in any other country, no patent can be obtained in this country. The writer believes he was the first to discover the use of static transformer control of an arc welding generator.

This transformer arrangement of the old familiar series reactor is a wonderful improvement, theoretically and practically. In self-excited machines the discharge into the hands of the operator is dangerous. In separately excited sets, the insulation should be of a special nature to insure that this doesn't happen. The trouble lies in applying the induced voltage to the shunt field which has high values to counteract. The same effect can be had by applying this voltage to the series field and here the values are so low that many times them are still less than the arc voltage.

Very truly yours,
C. J. Holslag (M'19)
(President, Electric Arc Cutting & Welding Company,
152 Jelliff Ave., Newark, N. J.)

(Editor's Note: This letter is an extension of one phase of Mr. Holslag's letter which was published in Electrical Engineering for January 1932, p. 59.)

# Standards

## Proposed Electrical Definitions Now Available in Report Form

The report on the proposed "American Standard Electrical Definitions" upon which the sectional committee on electrical definitions has been working for over 3 years now is available in a pamphlet of 208 pages. The project, which had its initiation in 1928 in the recommendation of the A.I.E.E. standards committee, has been carried on in full accordance with the rules of procedure of the American Standards Association and under the sponsorship of the Institute.

This work required the formation of 17 subcommittees with a total personnel of about 120, the additional expert help sought increasing the number cooperating to over 300. The individual reports of the subcommittees have been widely circulated for criticism and comment in each of their several stages of development. Controversies on proper wording naturally have developed in many instances. In most cases, the subcommittees have been able to arrive at an acceptable solution within their own groups. In cases of overlapping fields the executive committee under the able guidance of Chairman A. E. Kennelly has been called into action. Even after the most earnest efforts to eliminate conflicting definitions, it will be noted that certain conflicts still exist. It was felt to be very desirable, however, to issue the report as it now stands with the hope that circulation in pamphlet form would result not only in obtaining still further suggestions of a helpful nature, but might lead perhaps to a solution of the questions still unsettled.

In collecting and compiling the definitions which served as the original basis of the committee's work, it soon became evident that there existed conflicting definitions of identical terms, all having the status of American standards. In most such instances the sectional committee on electrical definitions has selected what appeared to it to be the most desirable wording. In other cases it has been felt desirable to suggest for a term or concept a wording differing from an accepted standard. The object in view always has been the development for each term of a wording expressing the meaning generally associated with it in electrical engineering in this country. When possible, definitions have been generalized so as not to preclude the different specific interpretations attached to particular applications.

The sectional committee wishes to express its sincere appreciation of the spirit of cooperation which it has met on all sides, and acknowledges its indebtedness to all organizations and individuals having given so freely of their time and experience. The assistance obtained from glossaries issued by various technical organizations, particularly the British, and the experience of the secretariat on nomenclature of the International Electrotechnical Commission, have been particularly helpful.

The glossary in its present state is incomplete, but it is impractical to carry through the entire program at one time. The cost involved to date has been great; therefore it has been found necessary to make a nominal charge for copies. This price has been set at $1 per copy, with the usual 50 per cent discount to members of the A.I.E.E.

Address all communications to A.I.E.E. Headquarters, 33 West 39th Street, New York, N. Y.

# Personal

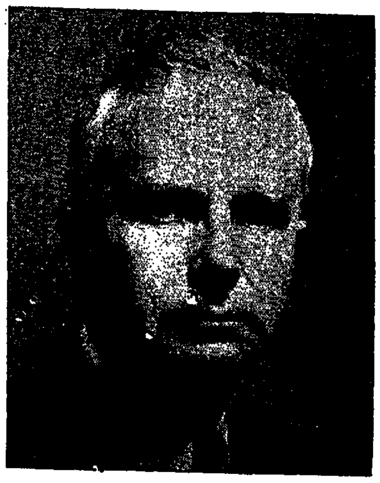
H. S. Osborne (A'10, F'21) who is now transmission engineer of the American Telephone and Telegraph Company, New York, N. Y., is to continue his chairmanship of the Institute's technical committee on communication for the ensuing year. He was born at Fayetteville, N. Y. From Massachusetts Institute of Technology he received his B.S. degree in 1908 and his doctor of engineering degree in 1910. During his college course he engaged summers in engineering positions which gave him a varied experience. In 1910 he joined the engineering department of the American Telephone and Telegraph Company as engineer in the transmission and protection department. Here he assisted in many developments in telephone and telegraph engineering, including quadded cable and the systematic study of interference in telephone circuits. In April 1914 he was made assistant to the transmission and protection engineer, and in this new office assisted in the establishment of the transcontinental telephone. Under the general direction of the transmission and protection engineer he also was in responsible charge of many important developments. In 1920 he was appointed transmission engineer and as such has assumed the responsibility for assisting all companies of the Bell Telephone System in connection with telephone and telegraph transmission and protection matters, advising regarding the proper use of new developments and carrying out exhaustive studies to determine the most desirable plant practises. Mr. Osborne has served as representative of the Institute on the American Standards Association from 1923 to date, at one time being assistant treasurer of the A.S.A. He also has served on the A.I.E.E. standards committee 1917–28 (chairman 1923–26); committee on education 1928–31; communication committee 1929–32 (chairman 1931–32); technical program committee 1924–25, 1927–29, 1931–32; and upon the electrical standards committee of the American Standards Association as an alternate representative of the A.I.E.E. 1931 to August 1932, when he was appointed a representative. Mr. Osborne now is vice-president and treasurer of the U.S. national committee of the International Electrotechnical Commission with which he has worked for many years. His memberships include the American Physical Society, the American Association for the Advancement of Science, the Acoustical Society of America, Engineering Foundation, Institute of Radio Engineers, and the Montclair (N.J.) Society of Engineers, of which he is also past-president. His contributions to technical literature have been numerous.

H. S. OSBORNE

E. J. Rutan (A'20, M'29) supervisor of the test bureau of the New York Edison Company, with which he has been associated for over a decade, has received reappointment as chairman of the Institute's technical committee on instruments and measurements for the current year. Brooklyn, N. Y., is Mr. Rutan's place of birth. After completing a course at Cornell University from which he received his M.E. degree with certificate in electrical engineering, he joined the test department of the New York Edison Company in 1919 as a tester. Within a short time he

K.L. HANSEN

S. L. HENDERSON



W. A. HILLEBRAND

E. J. RUTAN

had advanced to foreman; then he became general foreman, assistant superintendent, and ultimately superintendent. Since 1924 he has been in responsible charge of the company's test work. In 1930 the name of the test department was changed to test bureau and Mr. Rutan became supervisor; the work continued to cover all testing carried on by the company, including acceptance tests of all materials received in the store room, machinery for stations, and all equipment for transmission and distribution systems. Also all special testing for development and research purposes is conducted in this bureau to maintain electrical standards for the company in connection with primary standard cells, resistors, and potentiometers. Mr. Rutan was a member of the Institute's technical committee on protective devices, 1924–27; a member of the subcommittee on standards for measurements of voltages in dielectric tests, 1925–26; and in 1927 was appointed to the subcommittee called to draft standards for constant current transformers; his appointment to the technical program committee took place in 1930. Since 1926 he has served on the instruments and measurements committee, having been its chairman since 1930. As a member of the American Society for Testing Materials, he has served on its committee D9 on electrical insulating materials 1927–29, and now again in 1932.

**W. A. Hillebrand** (A'08, M'13) previously electrical engineer for the Ohio Insulator Company Division of the Ohio Brass Company, at Barberton, Ohio, a position which he had held since 1919, has returned to the academic field and in August 1932 will assume new duties in accepting a professorship in electrical engineering at the University of California, Berkeley, Calif. In a consulting capacity however, he will continue his affiliation with his commercial interests. Graduating from Cornell University in 1905, Mr. Hillebrand extended his studies to include a year at Stanford University, Calif. Through employment in the Pacific Coast office of the Western Electric Company 1906–7, he continued to broaden his experience. The period 1907–14 was occupied as instructor under Doctor H. J. Ryan at Leland Stanford University and as professor of electrical engineering at the Oregon State College, Corvallis, Ore. In June 1914 he joined the Pacific Gas and Electric Company (Calif.); for 2 years he was engaged with the Federal Telegraph Company (Calif.) in the manufacture of arc radio transmitters. His first identification with the Ohio Brass Company at Mansfield, Ohio, was as a commercial engineer, still centering his activities upon the Pacific Coast, but traveling over all parts of the United States and Canada, even spending some 8 months in Japan. In 1925 he went to Barberton, Ohio, as consulting electrical engineer for the Ohio Insulator Division of his company, thus returning to his native State. Mr. Hillebrand's place of birth was Perrysburg, Ohio, but he grew up in Washington, D. C. Besides his membership in the A.I.E.E., he is a member of the Institute of Radio Engineers and also of the Schweizerisher Elektrolechnischer Verein of Zurich.

**K. L. Hansen** (A'17) now carrying on a consulting engineering practise in Milwaukee, Wis., under the company name of K. L. Hansen Engineering Company, Inc., has been appointed to serve as chairman of the Institute's technical committee on electric welding for the current year, a committee of which he has been a member for the past 2 years. Mr. Hansen was born in Norway and came to the United States early in 1901. For 2½ years he worked in various shops in Chicago, most of the time for the Western Electric Company, assembling fan motors and arc lamps. In the fall of 1903 he entered the University of Illinois. From the summer of 1905 until early in 1906 he found employment with the Chicago Edison Company, first as splicer's helper in the underground cable department and later as substation operator. In February of that year he removed to East Pittsburgh, Pa., and joined the Westinghouse Electric and Manufacturing Company, working for a year and a half successively as wireman, tracer, and draftsman. His company then transferred him to the dynamo testing department where he remained for nearly 4 years or until he again was transferred, this time to the industrial engineering department, to become designing engineer for d-c motors and generators. He remained in the employ of the Westinghouse company until in the fall of 1919 he left it to join the Louis Allis Company (then the Mechanical Appliance Company) of Milwaukee. Here again he engaged in the capacity of designing engineer, this time for a-c and d-c motors and generators, later becoming chief engineer. It was upon severing his connection with the Louis Allis Company that he entered upon consulting and development work of his own. The Hansen arc welder, first built and marketed by the Northwestern Manufacturing Company, of Milwaukee, until the early part of 1932 and later taken over by the Harnischfeger Corporation of that city, was invented and designed by Mr. Hansen, whose own company, the K. L. Hansen Engineering Company, Inc., is now marketing it. He developed a number of arc welding processes, the Hansen arc torch being one of them. He also holds patents, jointly with another, on self-starting induction motors and self-starting compensated induction motors. During the past 5 years Mr. Hansen has given numerous addresses before technical societies and conventions, chiefly on the subject of arc welding and its many applications.

**S. L. Henderson** (A'12) division engineer of the power engineering department of the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., and since 1928 a member of the Institute's technical committee on electrical machinery, has received reappointment as its chairman for the current term of service ending August 1933. Mr. Henderson is a native of Roxbury, Mass.; upon completion of his public school work in Boston, he entered Massachusetts Institute of Technology. In July 1910 he joined the test department of the Westinghouse Electric and Manufacturing Company at East Pittsburgh, and by 1912 was holding a position of responsibility with that company. For a number of years he was in charge of turbine generator design for the Westinghouse company; his present work is in charge of design of large synchronous and induction motors. He also has been active as a committee-man for other technical bodies of professional importance, having served on the American Standards Association's sectional committee on rotating machinery; A.S.A. subcommittee on definitions; and subcommittee 1-C on wave shape, of the National Electric Light Association's joint committee on development and research in collaboration with the Bell System. In addition to his service on the electrical machinery committee of the A.I.E.E., Mr. Henderson has been active as a member of its subcommittee on synchronous machines.

**W. C. Smith** (A'07, M'26) succeeds **R. F. Monges** (A'08) to the position of district engineer of the San Francisco, Calif., office of the General Electric Company, June 1932. Mr. Smith has been with the company since 1905 in varying capacities, joining the organization the same year he was graduated from the University of Michigan. In 1907 he became a member of the transformer engineering department and until 1918 worked both at Pittsfield, Mass., and Schenectady, N. Y., supplementing this experience with 2 years spent in special investigations for his company at Denver, Colo., before taking office at San Francisco as transformer, meter, and regulator specialist. He has been Mr. Monges' assistant for the past year. In 1925 he was awarded the Coffin Medal, which is given annually by the General Electric Company, "for the most signal contributions toward increase in efficiency or progress in the electrical arts"; he is past-chairman of the company's Pittsfield Section, and recently was elected vice-chairman of the A.I.E.E. San Francisco Section, which he already has served during the past year as secretary. Other organizations to which he belongs are the San Francisco Electrical Development League, the San Francisco Engineers' Club, the Pacific Coast Electrical Association, and the Astronomical Society of the Pacific Coast.

**W. J. Mowbray** (A'03, F'31) previously operating as meter engineer at Cranston, R. I., and for the period 1919–30 research and test engineer as well as educational director for the Narragansett Electric Lighting Company of Providence, R. I., now has received his appointment as instructor in electrical engineering at the Rhode Island State College, at Kingston, R. I. During the whole of the above mentioned period Mr. Mowbray was serving the New England Section of the National Electric Light Association on its meter committee, of which he for one year was chairman; he also was a member of the A.I.E.E. instruments and measurements committee 1924–29.

**L. A. Magraw** (A'07, M'13) who at a recent conference was chosen to serve as president of the National Electric Light Association's Southeastern Division, has relinquished the presidency of the South Carolina Power Company, of Charleston, S. C., to become president of the Central Illinois Public Service Company, Chicago, Ill. Mr. Magraw received his degree of B.S. in E.E. from Worcester Polytechnic Institute; his achievements in electrical engineering have been outstanding for over 20 years, most of them having been in the South where he has been active since 1909.

**R. E. Doherty** (M'27) who last year resigned from his many years of service as consulting engineer of the General Electric Company, Schenectady, N. Y., to become professor of electrical engineering at Yale University, New Haven, Conn., continues his chairmanship of the Institute's education committee for the year following August 1, 1932. Mr. Doherty's native State is Illinois; he was graduated from the University of Illinois in 1909, at that time receiving his B.S. degree, and later, in 1921, his M.S. was won from Union College (Schenectady, N. Y.). He entered upon the General Electric Company's training course at Schenectady in 1909 and for 2 years was occupied in its test department. At the end of that time he was transferred to the a-c engineering department as proposition designing engineer. Here his work was observed by C. P. Steinmetz, who in 1920 chose Mr. Doherty as his assistant. It was while engaged in this work that he took his postgraduate course at Union College. The next year he became consulting engineer of the General Electric Company. In addition to duties devolving upon him as consulting engineer he has had charge of an advanced course in engineering specially planned by his company for a small and selected group of college graduates. This, a 3-year course, is practical professional work. He also was a member of the General Electric Company's general education committee. Institute committees upon which Mr. Doherty already has served are: education 1918–19, 1926–28, 1931–32 (chairman); electrophysics 1924–26; power transmission and distribution 1928–29; and technical program 1931–32. He also has served as chairman of the Institute's Schenectady (N. Y.) Section 1926–27. Mr. Doherty's contributions to technical literature have been numerous, both as regards papers of his own preparation and his discussion of those presented by others.

R. E. DOHERTY

**W. P. Taylor** (A'26) who ever since his graduation from Johns Hopkins University in 1923 has been associated with the Consolidated Gas, Electric Light and Power Company, at Baltimore, Md., was chosen to receive the 1931 A.I.E.E. Middle Eastern District prizes for both best paper and initial paper for his contribution entitled "Locating Power Cable Faults by Means of a Constant-Current Transformer With Short-Circuiting Switch." Mr. Taylor was born at Waterbury, Conn., but practically all his life has been spent in the state of Maryland. Prior to attending Johns Hopkins University, he spent 4 years in study in the grade schools of Stockton, Md.; his graduation from Johns Hopkins in 1923 was with the degree of B.E. in E.E. Immediately thereafter his work with the Consolidated Gas, Electric Light and Power Company of Baltimore started with his assisting in the conducting of tests on all kinds of electrical apparatus in the company's research and test departments. His present work covers chiefly the planning and conducting of tests on electrical appliances. One of the special investigations conducted was an attempt to determine the comparative life of various rubber compounds used as insulation for wire; another a study of power cable fault locating in an effort to eliminate some of the troubles commonly encountered in this field.

W. P. TAYLOR

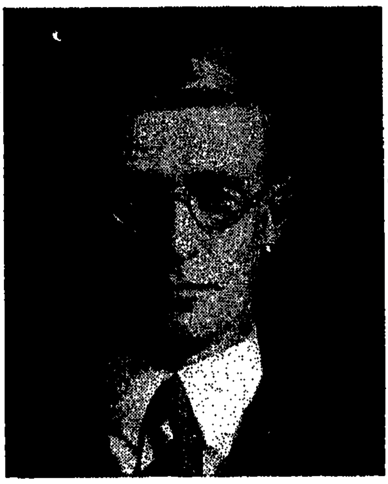
**R. F. Monges** (A'08) for 35 years district engineer of the San Francisco, Calif., office of the General Electric Company, retired as of June 1932. He is succeeded by W. C. Smith (A'07, M'26), who has been with the company as transformer sales engineer and Mr. Monges' assistant. Prior to becoming district engineer, Mr. Monges had held office with the company as assistant engineer for 8 years; he also had spent 2 years in the G. E. test department. This was immediately after his graduation from an electrical engineering course which he took at the University of California.

**C. E. Smith** (A'32) who during 1930–31 was student engineer for the RCA Victor Company, Inc., at Camden, N. J., working in the company's development and research laboratories, now has achieved the position of electrical engineer for The Radio Air Service Corporation, at Cleveland, Ohio, having been graduated last June from Ohio State University with the degree of M.S. in electrical communication engineering.

**W. R. Thorson** (A'26) who at one time was superintendent of electrical distribution for the Consumers Power Company, at Hudson, Mich., and later was in the distribution engineering department of that company at Jackson, Mich., now has been made superintendent of public works at Waverly, Ia.

**Vannevar Bush** (A'15, F'24) who recently became vice-president and dean of engineering at Massachusetts Institute of Technology at Cambridge, Mass. (see

Electrical Engineering, April 1932, p. 286, for a brief record of Doctor Bush's professional record), recently received reappointment as chairman of the Institute's technical committee on electrophysics. Doctor Bush already has served an unbroken record since 1924 upon this committee; his chairmanship dates from 1931.



VANNEVAR BUSH

G. M. Griffith (A'23) intermittently during the past 6 years has been identified with Latin-American utilities in Cuba, Costa Rica, and Venezuela; now he has returned to Atlanta, Ga., where he was once in the engineering department of the Georgia Railway and Power Company, to open a consulting engineering office of his own.

A. L. Abbott (A'06, M'13) engineer of the Society for Electrical Development, New York, N. Y., recently assumed the title of engineer of the uniform legislation department of the National Electrical Manufacturers Association, New York, N. Y.

D. McK. Greer (A'31) who was engineer in the watthourmeter section of the meter engineering department of the Westinghouse Electric and Manufacturing Company, at Newark, N. J., recently became an engineer of the American Instrument Company, in Washington, D. C.

C. A. Brown (A'23) who has been doing consulting engineering work for the Union Gulf Line, New York, N. Y., now is southeastern sales representative for the De La Vergne Engine Company, in Philadelphia, Pa.

C. M. Burrill (A'25) has left the position of research engineer with the Rogers-Majestic Corporation, Ltd., Ontario, Can., to return to the RCA Victor Company, Inc., of Camden, N. J., where he will serve in the research division.

J. L. Carr (A'24) for the past year or so salesman for the General Electric Company at Washington, D. C., has joined the Potomac Electric Power Company of that same city according to notice just received at Institute headquarters.

C. I. B. Henning (A'13) past-president of the Sporting Arms and Ammunition Manufacturers' Institute, New York, N. Y., and a stockholder in various corporations in this field of activity, recently retired from business.

Alfred Ruttiman (A'15) who has been serving the Florence Stove Company of Gardner, Mass., as research engineer, recently became experimental engineer for the Alaska Freezer Company, of Wichendon, Mass.

W. G. Woolfolk (M'16) who has been doing consulting engineering work under the name of W. G. Woolfolk and Company, Chicago, Ill., recently became president of the Detroit City Gas Company, at Detroit, Mich.

F. A. Davis (M'31) who has been with the Telephone Bond and Share Company, Kansas City, Mo., now has joined the Portsmouth Home Telephone Company, at Portsmouth, Ohio.

E. R. Hartman (M'31) who has been associated with the Telephone Bond and Share Company, at Kansas City, Mo., recently joined the Nebraska Continental Telephone Company, at Columbus, Neb.

J. W. Hancock (A'10) who is manager of the Appalachian Electric Power Company at Roanoke, Va., has been elected president of the southeastern geographic division of the National Electric Light Association.

W. H. Sammis (A'20) of New York, N. Y., recently was elected a director of the Consumers Power Company, Jackson, Mich. Mr. Sammis formerly was located in the general offices of that company at Jackson.

# Obituary

Thaddeus Reynolds Beal (A'03) president and general manager of the Central Hudson Gas and Electric Corporation, Poughkeepsie, N. Y., died August 10, 1932, of a heart attack which came upon him while he was at Nantucket, Mass. Mr. Beal was born in New York City, June 1870, and was educated at the College of the City of New York, graduating from its engineering course in 1889. His father, William Beal, was the founder of the original power company in Newburgh, N. Y., and for 12 years, through a series of consolidations of Poughkeepsie, Newburgh, and New York City organizations, Thaddeus Beal found practical experience with the gas and electric business of these cities. The Central Hudson Corporation was a culmination of some of these consolidations, the merging of the Poughkeepsie Power Company and the Newburgh Gas and Electric Company in 1911 forming the nucleus. Of this new firm, formed after the death of his father, Mr. Beal was general manager, as he had been consecutively of the Newburgh Light, Heat, and Power Company and the Poughkeepsie Light, Heat, and Power Company. On the first of January 1927 he became president of a consolidation involving some 65 eastern gas and light concerns. Mr. Beal was a member of the American Gas Institute, the Society of Gas Lighting, the Engineers' Club of New York, Delta Kappa Upsilon, and was on the executive board of the New York Y. M. C. A. He had also served as a naval officer during the Spanish-American War.

William Ramsey Hendry (A'05) for the past 25 years active in the electrical industry upon the West Coast, and at the time of his death proprietor and manager of the W. R. Hendry Company at Seattle, Wash., died recently at his home in that city. A native of Montreal, Can. (1875), he removed to Tacoma, Wash., in 1892 and engaged with the construction department of the Thompson-Houston Electric Company. Early in 1893 he was transferred to the general repair shop of the General Electric Company in Portland, Ore., but in the fall of the year he returned to Tacoma and entered the high school for a 2-year period. He then became armature winder for the City Park Railway Company, Tacoma, for 2 years, after which he was identified with the Bernard's Bay Mining and Milling Company, Seward City, Alaska, for a year, in charge of the installation and operation of lighting and power machinery. His next affiliation was with the Coney Island and Brooklyn Railroad Company, Brooklyn, N. Y. The latter part of 1900 found him chief electrician for the Merritt Air Brake Company of New York City, a position which he held until his return West in 1902 to work in the construction and operating departments, and later the contracting department, of the Snoqualmie Falls Power Company, Seattle, Wash. His own Company was established in 1911.

George Frame Ferguson (A'15, M'28) late of Arthur D. Riley and Company, Ltd., Auckland, N. Z., where he held the office of consulting and construction engineer, died there recently. Auckland was Mr. Ferguson's birthplace; there too he received his early education at the so-called "state school" and a course in electrical engineering at the local technical college. In 1906 when 20 years of age he came to the United States and engaged with the Commonwealth Edison Company of Chicago, Ill., remaining there until 1910. Returning to New Zealand, the period from 1911 to 1925 was spent in various hydroelectric undertakings as assistant engineer on the Horo Hora development, the Lake Coleridge works, in the government's hydroelectric department at Tasmania, in charge of high tension design and construction, and with the Southland Power Board on hydroelectric works and distribution. He then returned to Auckland to become manager of the electrical department of Arthur D. Riley and Company, Ltd., representing Ferranti, Ltd., the Telegraph Condenser Company, the Electric Construction Company, and others, carrying out some of the largest contracts in New Zealand, where he was recognized as a capable member of his profession. He was an associate member of the Institution of Electrical Engineering, London, Eng., and a chartered, registered electrical engineer.

H. O. SWOBODA (A'14, M'27) consulting electrical and mechanical engineer at Pittsburgh, Pa., and president and treasurer of H. O. Swoboda, Inc., died June 30, 1932, in the Pennsylvania Hospital of that city after a short illness. Mr. Swoboda was born in Buchholz, Saxony, Germany, February 4, 1870, and received both his primary and early technical training abroad. He was a graduate of the technical university at Darmstadt, Germany. From 1890 to 1892 he was employed by Siemens and Halske, Berlin, Germany, as electrical engineer. He then came to the United States and joined the General Incandescent Arc Light Company of New York, N. Y., as chief electrical engineer and general superintendent. From 1899 to 1902 he held a similar position with The Falcon Electric and Manufacturing Company; from 1902 to 1907 he was employed by the H. O. S. Engineering Company, at Newark, N. J.; dating from 1908 he was for 2 years consulting electrical and mechanical engineer in New York City. In 1910 he joined the Westinghouse Electric and Manufacturing Company at East Pittsburgh, as assistant superintendent, but in 1912, returned to his consulting work, establishing his own office in the city of Pittsburgh. Mr. Swoboda also has been a liberal contributor to scientific and technical literature. He was a registered professional engineer of the state of Pennsylvania, and his memberships included The American Society of Mechanical Engineers, the German technical society Technischer Verein, and the American Society for Steel Treating. His social activities embraced those of the Lincoln Club of Pittsburgh and the Pittsburgh Athletic Association.

RUDOLPH ROSENSTENGEL (A'05) professor of electrical engineering at Gettysburg College, Gettysburg, Pa., died suddenly August 1, 1932, as the result of an embolism. He was 61 years of age and was born in St. Louis, Mo. In 1894 he was graduated from an electrical engineering course at the University of Wisconsin, his earlier education having been acquired in the public schools of Madison, Wis. For 2 years after leaving college, Mr. Rosenstengel was with the Christensen Engineering Company of Milwaukee in the capacity of draftsman; later he also performed 2 years of similar work for N. A. Christensen, also of Milwaukee, still later spending a period of 8 months in the design of several small electric motors in connection with these same interests. He then joined the Brodessor Elevator Manufacturing Company, but a year and a half later severed this connection to identify himself with the Mechanical Appliance Company of Milwaukee. In September of the year 1905 he was chosen as instructor in mechanical engineering at the Michigan Agricultural College.

# Local Meetings

## Future Section Meetings

**Dallas**

September 19—Buffet supper at University Club. REPORT OF SUMMER CONVENTION, by O. S. Hockaday, delegate. TRIBUTE TO VICE-PRESIDENT G. A. MILLS AND DIRECTOR B. D. HULL, by J. B. Thomas. Response by Messrs. Mills and Hull.

**Lehigh Valley**

October 1—Inspection trip through the Reading Railway electrification at Philadelphia.

## Past Section Meetings

**Mexico**

POWER SALES AND THE ENGINEER, by J. M. Zilboorg, Cia Hidroelectrica Guanajuatense. E. F. Lopez, chmn., gave a report of the summer convention held at Cleveland, Ohio. Dinner. July 21. Att. 22.

**Montana**

Business meeting. July 19. Att. 8.

**Niagara Frontier**

Executive committee meeting. July 25. Att. 10.

## Past Branch Meetings

**Drexel Institute**

WIND POWER GENERATING STATIONS, by F. P. States, student. July 20. Att. 9.

FIXED RATIO SYNCHRONOUS FREQUENCY CONVERTERS, by S. I. Croney. August 3. Att. 9.

**University of Louisville**

ATOMIC ENERGY, by R. B. Craig, student, NEW TYPE ELECTRIC CLOCK, by L. B. Bryan, student.

# Employment Notes

## Of the Engineering Societies Employment Service

### Men Available

**Construction**

GRAD. E.E., 29; 5 yr. supervisory construction, design, estimating and field engg. experience on super-pwr. plants and substations; 4 yr. industrial power plant operation, elec. construction and maintenance experience; ry. electrification constr. experience. C-4428.

EXPERIENCED ELECTRICIAN. Col. grad. Wide experience in all branches of elec. installation and service including radio and photoelectricity, desires connection with movie studio. Location and salary no object. D-1309.

E.E. GRAD., 1928, U. of Kansas, 27, married, $2\frac{1}{2}$ yr. technical experience in telephone pole line constr. and maintenance with Am. Tel. & Tel. Co. Six months experience as city engr., 2 yr. experience in highway engg. and reinforced concrete design and construction. Available immediately, location, immaterial. D-1342.

OUTSIDE PLANT ENGR., 27, single, B.S. in E.E. from Sheffield Scientific Sch. in 1927. One yr. experience in testing d-c ry. car lighting equip., 4 yr. design and application of pole line and underground hardware for telephone plant. D-1305.

**Design and Development**

ENGR., 31; 12 yr. Bell system and govt. plant and field experience on sound picture, radio and telephone (manual, dial, repeater and carrier current) systems. Design and devpt. of manual and automatic elec. testing equip. Industrial applications of electron tubes. Available immediately. C-9376.

REFRIGERATION ENGR., 33, married, A.B., E.E., also member Phi Beta Kappa and Sigma Xi. Extensive experience in designing Ranco thermostatic relays, $1\frac{1}{2}$ yr. experience in study and design of humidity and room temperature control apparatus. Desires work with refrigerator mfr., or co. in air-conditioning field. Best of references. D-1310.

DEVPT. AND DESIGN ENGR., B.S., E.E., 35, married; 11 yr. experience elec. construction and design, also devpt., assembly, and testing of oil & gas elec. equip. including engine testing and devpt. of elec. control and engine cooling systems. Can assume full responsibility of devpt. program. Available immediately. Location, immaterial. D-1277.

MECH. AND ELEC. ENGR., inventive, analytical, mature; 30 yr. designing engr. G.E., Crocker Wheeler and Westinghouse. Wide experience in motor control systems and apparatus. Inventions extensively used. Desires devpt. work in same or related fields or as consultant. Salary to suit location and duties. A-2110.

E.E. GRAD., single, 8 yr. switchboard and motor control designing, pricing, specifying, and writing specifications. Qualified designer, estimator, inspector, or genl., resident, operating and consulting engr. Excellent references from 2 elec. mfg. companies. Available immediately. Location, U.S. C-3530.

E.E., 32, col. grad., $8\frac{1}{2}$ yr. diversified experience including test and central station engg. with G.E. Co.; design, construction and system devpt. for a large utility; plant engg. with a large industrial concern; also $1\frac{1}{2}$ yr. small plant power and refrigeration operation and maintenance. C-5727.

DISTRIBUTION, design, or mfg. engr., E.E. grad., 27, married, 6 yr. experience with Westinghouse on distribution, special and small transformer designs. Desires responsible position as transformer design, devpt. or mfg. engr. of elec. engr. for mfg., utility, holding co., or where knowledge of a big company's methods may be used. Available immediately. D-963.

E.E., univ. grad., elec. pwr. experience, both design work and construction and maintenance work, desires position with pwr. or mfg. organization offering permanent or temp. position in office or field. B-1923.

**Executives**

INDUSTRIAL AND CENTRAL STATION ENGR., Cornell grad. Married, 15 yr. practical experience on design, installation and operation of manual and automatic elec. control for industrial and central station application. Available Sept. 1. Capable executive. D-1273.

PLANT ENGR., ASST. EXEC., E.E.-M.E. grad., 20 yr. broad experience in and with mech. trades on construction and plant maintenance; in modern design, manufacture and installation of equip.; design and layout of plant. Special training and experience in metallurgy, concrete, elec. arc welding, building constr., specifications, business mgmt., sales. C-4519.

EXEC. ASST. available, E.E. grad., 37; 12 yr. utility experience. Appraisal work of power plants, substations, transmission and distribution systems, rate investigations covering industrial service, residential and commercial, cost studies, statistical research, operation in plant, equip. and lines. G.E. test course. B-9782.

INDUSTRIAL PLANT ELEC. EFFICIENCY EXPERT, 36, with steam engg. and elec. engg. diploma and 12 yr. industrial plant experience, desires position with opportunity. Will go anywhere. B-7004.

ELEC. AND CHEM. ENGR., experienced in tel. and tel. communication including devpt., mfg., and operation, 37, married. Can fill any suitable position requiring initiative, wide experience, and a large acquaintanceship in the communication industry. C-1971.

E.E. GRAD., 38; 17 yr. experience, construction, installation, maintenance, inspections, tests, pwr. plants and substations, distribution (high and low tension), 1 yr. operating, familiar with So. Am., speaks several languages. Available at once, home or abroad. Best of references. C-2021.

E.E. GRAD., 46, married. G.E. test followed by 20 yr. experience in transformer design and manufacture with the large companies. Desires connection with elec. mfr. or pwr. co. Available on short notice. C-8806.

E.E., M.I.T.; 1921; Columbia Univ.; 32, married. Engr., consultant, editor, tech. sales rep. Broad exper., U.S., Canada, communication apparatus, circuits; telephone, telegraph; voice, carrier, radio frequency; amplifiers, sound pictures, program transmission. Built, directed electro-acoustic testing lab. Experience, employment; patent consideration, court testimony; magazine, newspaper publishing; lecturing; publicity. Prefer New York. D-1315.

E.E., B.S. in E.E., Iowa St. Col. 1929; '32, single, worked way through col. 3 yr. group leader, Westinghouse transformer test, including power, distr.; and instrument transformers, a-c welding outfits, special apparatus. Liberal shop experience. Interested, exec. position, supervision, design, and constr.; inspection and testing. References. Location immaterial. Available immediately. D-1081.

E.E., univ. grad., pwr. experience, desires position with pwr. or mfg. co. Devpt. work preferred, but not essential. B-1923.

E.E., 20 yr. experience in design, maintenance, and construction of central and substations; equip. of buildings and industrial plants, desires a connection with utility or factory. Specialized work, in protective circuits, metering problems; automatic elec. control of conveyors, substations, condensers, and combustion systems for boilers. B-7290.

ENGR.-ACCOUNTANT. E. E. deg., 1912, special study in accounting, exec. experience, 10 yr. with pub. serv. commission and 7 yr. mgmt. corp. making appraisals, audits, rate studies, and investigations all classes utilities both U.S. and Latin America. Available soon. C-2569.

**Inspection**

GRAD. E.E., 1927, single, 3 yr. experience as inspection engr. and supervisor; 1 yr. of meter testing. Location in the East. Available immediately. C-3213.

**Instruction**

M.E.; M.S., 26, single. Four yr. experience in telephone work. Desires teaching or engg. work of any nature except sales. Available immediately. Location, immaterial. D-1225.

GRAD. E.E., 7 yr. teaching, 18 yr. practical experience. Last 12 yr. in mechanical lines; steam, gas, air, and water engg., ore and alkali plants, handling, conveying, and process equp. Taught heat pwr. engg. at Oregon St. Col. and elec. lab. at Beaune, France. Location, immaterial. A-3651.

E.E. GRAD., 1930, 27, single. Fourteen months G.E. test. Five months assignment in G.E. research lab. Experience also includes teaching E.E. subjects for 7 months. Desires position as instructor in E.E. subjects or physics with opportunity of taking grad. work. D-136.

PROFESSOR, B.S. (E.E.), M.S., and E.E. deg., Colorado and Cornell, 38, 9 yr. experience teaching elec. engg. subjects and engg. physics, 9 yr. practical experience in varied fields. Available for Sept. D-1351.

INSTRUCTOR, elec. lab. and trade training. grad. Lowell Inst. auspices M.I.T., elec. and industrial mgmt. courses, Mass. and Conn. teacher's certificate, 44, married. Twenty yr. elec. utility operating experience, maintenance electrician, contracting, secy. Elec. Lines Club, chairman meeting and papers committee, Mass. Assn. Municipal Elec. Inspectors. C-8411.

PHYSICIST, 49, married., Ph.D. Seven yr. univ. teaching experience, Yale, U. of Ill.; 1 yr. study, Rutherford, England. Fifteen yr. experience, directing, carrying on research in heat transmission and phases elec. and mech. lines 2 large industrial concerns. Present position being discontinued. Desires position of responsibility, univ. teaching or in industrial research. D-1366.

E.E. GRAD., 26, single, excellent physical condition. One yr. experience installation, testing telephone exchange equip. Three yr. teaching pub. sch. Grad. small bus. col. Considerable training, experience, selling. Not afraid of hard work. Interested in position requiring engg. knowledge or teaching experience. Excellent references. Correspondence invited. Location, immaterial. Available immediately. D-1076.

E.E., married, good health and strong physique, M.S. in E.E. 1932 with thesis on mercury tube voltage regulator, 3 yr. teaching engg. drawing and descriptive geometry in large univ., clever in adjustment and repair of mech. and elec. devices, machinist experience. Westinghouse grad. student. Prefers teaching position, but anything considered. D-445.

MECH.-ELEC. ENGR., 32, 4 yr. Cornell design instructor; 5 yr. Allis-Chalmers design; liberal shop experience; 5 yr. cooperative apprenticeship. Will consider anything, anywhere, now available. Salary open. D-122.

**Junior Engineers**

E.E. GRAD., U. of Pittsburgh, 1932, single, 27. Five yr. various elec. experience including wiring, radio, substation operation and maintenance, experience on oil circuit breakers, and several months' experience testing pwr. relays. Prefers position with utility. D-1249.

GRAD. E.E., 29, single. Desires connection with constr., utility, mfg. or holding co. Five yr. experience designing both a-c and d-c motors with large elec. mfg. co. Aggressive and capable of assuming responsibility. Excellent references. Available immediately. D-944.

RECENT RENSSELAER POLY. INST. GRAD., E.E., 1932; Sigma Xi; single; 22. Summer experience in engg. and standardization dept. of large mfg. concern. Desires work in any engg. field. Salary and location secondary. Available immediately. D-1296.

B.S. in E.E., 1931, Armour Tech., 23, single, experience, 6 mos. telephone, 3 mos. G.E. Co. student, 7 mos. utility co. student. Speaks German well, wants work. Salary secondary. Location, immaterial. D-1072.

GRAD. E.E., B.S., A.B. from a foreign univ., desires position with a mfg. co. or a utility in transmission, distribution or testing lab. or elec. ry. Available on short notice. Location, immaterial. D-1110.

E.E. GRAD., '32. Married, 24. Experience includes 6 months asst. radio engr. at broadcast station, amateur 3 yr., 6 months auto. mech. Holds radio broadcast and amateur licenses. Very good references. D-1360.

E.E. GRAD., 1932, Mississippi St. Col., single, 30, excellent health. Two yr. marine electrician, U.S. Navy; 2 yr. engr. and operator local lt. and heat plant, Union Univ., Jackson, Tenn.; illumination experience. Desires position with future. Available immediately—anywhere, South or West preferable. D-1269.

B.S. in E.E. 1932. Ohio Univ., 22, single. Desires position with utility or mfg. concern. Wiring and repair experience. Particularly interested in work with motors and generators. Available immediately. Location, immaterial. D-1280.

B.S. in E.E., 1931 grad., single, 24, desires position in elec. engg. preferably teaching or research. Two summers' experience with elec. contracting co. Was grad. asst. at col. this yr. High scholastic record. References. Salary and location secondary. Available immediately. D-1259.

E.E., 27, single, available Nov. for responsible position abroad, British West Indies preferred. Eight yr. practical experience in large Canadian repair shop handling all types pwr. equip. Three yr. executive and sales. Able to take charge repair dept. industrial concern or pwr. co. Knowledge of industrial engg. Excellent references. C-8336.

B.S. IN E.E. 1932, 23, single. Five yr. cooperative course, 18 mos. experience with telephone and pwr. co. Winner first award South Eastern A.I.E.E. convention. Salary immaterial at start Available at once, location, U.S. D-1304.

B.S. IN E.E., New York Univ., 1932, single, 21, member Tau Beta Pi. One summer's experience in test dept. United Electric Lt. & Pwr. Co. Industrious, intelligent worker who can take and give orders in right manner. Location, salary immaterial factors. C-9434.

E.E. GRAD., '28, B.S. '27. Four yr. with large mfg. concern. Special training in engg. fundamentals (elec. and mech.) as preparation for devpt. work. Desires position with mfg. concern, utility, teaching or as asst. to consultant. D-1290.

E.E. GRAD., 1931, Mid-West univ., 25, single, 2 yr. experience with elec. contracting and constr. co. Desires position in the illuminating field. Location, immaterial and available immediately. D-1365.

E.E. GRAD., Purdue, 1930. Single, 24. Two yr. communication experience and training with Am. Tel & Tel. Co., including outside line and cable construction; test room operation, carrier systems, etc., also Morse telegraphy. Not afraid of hard work. References gladly furnished. Available immediately to go anywhere. D-1075.

E.E. GRAD., 29, married. Five yr. with Western Elec. Co. Experience most valuable for communication engg., but also desires work in research lab. or any engg. field. Good scholastic record. Available anywhere on short notice but East preferred. D-1323.

M.S. in E.E., 1932, 22, single. Technical experience with X-ray and glow discharge tubes. Desires position in teaching or engg. field. Salary and location immaterial. Available after Sept. 10. D-1375.

B.S. in E.E., 1932. Married. Some experience in surveying. Location, immaterial. Prefer work in elec. field but will consider anything. Available immediately. D-1373.

B.S. in E.E., 1932, 22, single. Good references, desires engg. work with future. Location, immaterial. Available at once. D-1374.

**Maintenance & Operation**

FOREMAN, 37, single, desire foreign or domestic connection involving constr., operation or maintenance (elec.) or pwr. houses, substations or industrial installations of all voltages and capacities. Has had 3½ yr. experience in Latin America with Am. holding co. Available now. Location, immaterial. D-1343-328-C-1-San Francisco.

ELEC. MAINTENANCE ENGR.-operator-elec. foreman-inspector-electrician-tech. grad., 30. Twelve yr. experience. All types industrial and mining equipment. Construction and operation of hydroelectric, steam, pwr. plant, outdoor switching stations; transmission lines distribution and telephone systems; elec. ry. Seven yr. Latin America. References. Knowledge Spanish, Portuguese. D-1353.

## ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.
San Francisco

205 West Wacker Drive
Chicago

31 West 39th St.
New York

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

**Men Available.**—Brief announcements will be published without charge; repeated only upon specific request and after one month's interval. Names and records remain on file for three months; renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

**Opportunities.**—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

**Voluntary Contributions.**—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

**Answers to Announcements.**—Address the key number indicated in each case and mail to the New York office, with an extra two-cent stamp enclosed for forwarding.

**Patents**

PATENT ENGR., comprehensive experience including preparation patent applications, analysis patents for essential scope, tests marketed products to ascertain infringement, test and testimony in litigation. Familiar, elec., acoustic, wire communication, radio fields. Qualified by basic preparation Ph.D. in physics to do effective work in other engg. branches. Can conduct research if desired. C-4919.

**Research**

RESEARCH ENGR., B.S. in E.E., Pennsylvania St. Col., 1930; 1½ yr. experience as statistician-research engr. on industrial and marketing surveys. Can speak Spanish fluently. C-7551.

INVENTOR, just completed invention of office machine of cash register type desires income. Exceptionally qualified for inventive, design or research work and has widely varied experience including automobiles, elec. equip., and utilities. Education, E.E. and business administration. G.E. test. No better or harder worker can be found. Any location. C-9820.

E.E., M.S. '29, Ph.D., Calif. Inst. Tech. '32. Research work dealt with measurement lighting currents, use high and low frequencies and surges in dehydration of crude oil emulsions, and cracking of gasolines. Two yr. experience, electrician, pwr. plant test engr. Desires position, where experience, and training will be useful. Single, 28. D-1350.

E.E. GRAD., '23 Sc.M., M.I.T. and Harvard '28; Sc.D. M.I.T. June '32; 38, single; 9 yr. practical experience, pwr.-and-communication engg. Two yr. testing course. Speaks Swedish, English, German; reading knowledge French. Desires position preferably in line of communication engg. Available. Location, immaterial. D-747.

PUB. UTILITY RESEARCH; U. of Ill. grad., 36, married. Twelve yr. experience consulting field charge of transit and street traffic operating surveys, pwr. and other utility rate, regulation, franchise, valuation, and financing investigations, most principal eastern, mid-west and southern cities. Open to either permanent or good temporary assignment. B-446.

MEDICALLY INCLINED 1930 E.E. grad., industrial experience, desires elec. work, hospital, medical school or research lab. where experimental or practical work is being done in applied elec. Studied electrotherapeutics past year. Salary secondary to opportunity to study this special application of electricity. Intends taking academic work in this field. C-9497.

E.E. GRAD., Bucknell 1928. Single, 26. One yr. experience research dept., of large engg. corp., 3 yr. experience and training with Am. Tel & Tel. Co. including outside line and cable constr. and testing methods; also familiar test room operation and methods. Excellent references. Available immediately. Location, immaterial. C-4528.

**Sales**

SALES ENGR., E.E. deg., 30, single, 3½ yr. high grade sales experience selling industrials and educational institutions, contacting distributors branches, etc. Good correspondent. 1½ yr. engg. dept. large utility. 1½ yr. elec. testing lab. Some elec. contracting. Desires position of promise with mfg. concern. Mid-West preferred, not essential. Available one month. D-1344.

ASSOC. A.I.E.E., single, 26, E.E. Grad. J. H. U. Experience: 6 mos. switchgear testing; 3½ yr. as motor control engr., including shop, engg., and sales work; 6 mos. as jobbers' salesman. Familiar with industrial control design, application, and estimating. Desires any engg. position with opportunity. East preferred, not essential. D-1368.

GRAD. E.E., 1926, Columbia, 29, married. Practical experience with pwr. and telephone companies. One yr. lab. asst. in elec. classes and 4 yr. instructor in evening classes in col. mathematics. Engg. sales experience. C-9308.

E.E. GRAD., 29, single. Seven yr. with elec. utilities covering distribution planning, operation, customer contacts, etc. Substation design, equip. recommendations, voltage studies, relay setting. Eighteen months' experience changing system from 30 to 60 cycles, involving industrial electrification; covering uses of electricity. Can write reports. Suited for pwr. sales work. Available immediately. C-5960.

B.S. IN E.E., Professional Engr., N. J., 34, married. Storage battery, automotive elec. sales and service, 5 yr. heat and sound insulation sales engg. contacting architects, engineers, job supervising, 4 yr. steel corp. sales engr. contacting architects, engr., New York, New Jersey, 3 yr. inventive ability and experience. C-75.

NATURAL GAS HEATING, VENTILATING, AND APPLIANCE ENGR., 27, grad. B.S. in E.E. Two yr. experience in design, installation, and maintenance of gas heating plants. Formerly on sales engg. staff of western utility. Available immediately. C-9525.

SALES ENGR., single, grad. E.E.; 7 yr. experience selling elec. equip. (motors, generators, etc.) to industrial plants located in the East and Mid-West territories and 13 yr. connection with large utilities in industrial sales work and as supervisor of pwr. sales dept. C-5546.

GRAD. ENGR., 25, 2 yr. practical work, research and testing. Capable of speaking, reading and writing Spanish fluently. Available at once, willing to travel if necessary. Class of 1930. Willing to study under sales engr. as applicant has 2 yr. selling experience. C-9002.

# Membership

## Recommended for Transfer

The Board of Examiners, at its meeting of July 27, 1932, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the acting national secretary.

**To Grade of Fellow**

Dates, Henry B., prof. of e. e., Case Sch. of Ap. Sci., Cleveland.
Dows, Chester L., head elec. and photometric measurements, Genl. Elec. Co., Cleveland.
Enfield, Wm. L., mgr., Incandescent Lamp Dept., Genl. Elec. Co., Cleveland.
Jansky, Cyril M., prof. of e. e., Univ. of Wisconsin, Madison.
Lincoln, John C., chmn. of board, Lincoln Elec. Co., Cleveland.
McMillan, Fred O., research prof. of e. e., Oregon State Col., Corvallis.

**To Grade of Member**

Berry, Henry P., preliminary plans engr., Chesapeake & Potomac Tel. Co., Charleston, W. Va.
Bolsterli, Arthur A., elec. engr., Safety Car Heating & Lighting Co., New Haven, Conn.
Carville, Ellsworth M., small motor design engr., Westinghouse E. & M. Co., Springfield, Mass.
Charest, J. C., supt. of distribution, Pa. Pwr. & Lt. Co., Hazleton.
Clark, Sam W., engr. and supt. of pwr. plant construction, Calle Gante No. 15, Mexico, D. F.
Congleton, Ray T., proprietor, Congleton Engg. Co., Dayton, O.
Crymble, Alfred C., pres., Crymble Elec. Co., Inc., Bristol, Va.
Del'Homme, Laurence, asst. engr., Houston Ltg. & Pwr. Co., Texas
Eide, Randolph, pres., Ohio Bell Tel. Co., Cleveland.
Frazier, Richard H., asst. prof. of e. e., Mass. Inst. of Tech., Cambridge.
Gill, Peter Clark, supt. of trans. and distribution, B. C. Elec. Ry. Co., Vancouver, B. C.
Harrington, Charles A., e. e. dept., Cleveland Elec. Ill. Co., Ohio.
Hattingh, Johannes T., tech. asst. to chmn. of electricity supply commission, Johannesburg, S. Africa.
Hibshman, Nelson S., asst. prof. of e. e., Lehigh Univ., Bethlehem, Pa.
Hill, Owen E., supervising devpmt. engr., Western Elec. Co., Inc., N. Y. City.
Hover, Ernest W., design engr., Central Hudson Gas & Elec. Corp., Poughkeepsie, N. Y.
Jansky, C. Moreau, Jr., consulting radio engr., Jansky & Bailey, Washington, D. C.
Keiffer, Lawrence R., elec. engr., Genl. Elec. Co., Cleveland, O.
Kubiak, Henry J., instructor in e. e., Univ. of Wisconsin, Madison.
Mason, H. Russell, prof. of e. e., Southwestern Louisiana Inst., Lafayette.
Payne, John H., elec. engr., East Orange, N. J.
Pearson, Harold E., switchgear commercial engr., Genl. Elec. Co., Phila., Pa.
Porter, Vance G., dist. mgr., Central Pwr. & Lt. Co., Bay City, Texas.
Ranson, Richard R., elec. engr., Cutler Hammer, Inc., Milwaukee, Wis.
Schnautz, Wm. J., outside plant engr., N. Y. Tel. Co., Buffalo, N. Y.
Spring, Ernest W., research engr., Detroit Edison Co., Mich.
Staehle, Daniel, Jr., elec. engr., Frank Adam Elec. Co., St. Louis, Mo.
Stine, Wilmer E., research and welding engr., Lincoln Elec. Co., Cleveland, O.
Wilson, Archibald F., asst. vice-pres., Ohio Bell Tel. Co., Cleveland.
Youngstrom, N. C., member tech. staff, Bell Tel. Labs., Inc., New York.

## Applications for Election

Applications have been received at headquarters from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the acting national secretary before Sept. 30, 1932.

Berthold, R. V., Assonet Beach, Mass.
Busby, T. A., The Commonwealth & Southern Corp., Birmingham, Ala.
Hanson, V. A., (Member) Mechanical Pwr. Engg. Associates, Bklyn., N. Y.
Hatto, S. G., Shell Oil Co., Seattle, Wash.
Izzi, V. A., Bd. of Transportation, City of N. Y., N. Y.
Kendall, Ralph M. (Member), Amer. Tel. & Tel. Co., 195 Bway., N. Y. City.
Miller, H. E., (Member) Westinghouse Elec. & Mfg. Co., Newark, N. J.
Mitchell, S. R., 1840 Lincoln St., Denver, Colo.
Niemann, A. W., Bell Tel. Lab., Inc., N. Y. City
Olsen, W. O., 1054 52nd St., Bklyn., N. Y.
Spiegel, W. F., Ry. Express Agency, Inc., Hoboken, N. J.
Stone, M., Westinghouse Elec. & Mfg. Co., Pittsburgh, Pa.
Strothman, R. A., 7 Laurel Ave., Summit, N. J.
Thicke, J. E., Aluminum Co. of Canada, Montreal, Quebec.
Turner, C. G., Kansas City Pwr. & Lt. Co., Mo.
15 Domestic

### Foreign

Alizo C., Antonio, Cia. Anoma, Planta Elect. de Valera, Est. Trujillo, Venezuela, S. A.
Beljabsky, A. G., (Member) North-Caucas Inst. of Energetics, Novocherkassk, U.S.S.R.
Bryant, A., Kenya & Uganda Govts., Nairobi, Kenya Colony, E. Africa.
Chan, S., 33 Wan Tsai Rd., Hong Kong, China.
Foulsum, W. C., 16 Bondoran Parade, Mont Albert, Melbourne, Australia.
Kesavan, V. K., Pwr. Station Kottayam, Travancore, So. India.
Rozario, J. F. T., Pub. Wks. Dept., Madras Govt., Madras, India.
Thampan, K. C., Pykara Construction Wks., Glen Morgan P. O., The Nilgiris, So. India.
Verma, R. P., Gaya Engg. & Elec. Pwr. Sup. Co., Ltd., Gaya, India.
9 Foreign

# Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the address as it now appears on the Institute records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Adams, Albert J., 950—18th Ave., Honolulu, T. H.
Blugerman, L. N., 227 N. 18th St., Phila., Pa.
Callen, R. J., Brunswick Recording Lab., 709—7th Ave., N. Y. City.
Cooper, Lamar S., 1936 Dallas St., Phila., Pa.
Dalas, F. L., Boulder City, Nev.
Deney, Roger W., 685 Sumner-Atlantic Ave., Forest Hills Boro, Pittsburgh, Pa.
Diamond, Harvey, Avenida Concepcion 105, Providencia, Santiago de Chile, S. Am.
Gooding, Chas. C., 1414 K St., Sacramento, Calif.
Keiser, Morris, 1025 King St., Alexandria, Va.
Morita, Kadzuo, c/o Chosen Hydro-Elec. Co., Kankyo-Nando, Korea, Japan.
Neander, M., 182 Pravy Bereg Nevy Kv. 51, Leningrad, U.S.S.R.
Nichols, E. D., 536 W. 3rd St., Erie, Pa.
Olsson, Oscar G., 361 Mulberry St., Williamsport, Pa.
Pearson, Ernest, 209 Brewster Rd., Scarsdale, N. Y.
Schroeder, G., Krivokolenni Pereulok No. 11-16, Moscow, U.S.S.R.

# Engineering Literature

## New Books
### in the Societies Library

Among the new books received at the Engineering Societies Library, New York, during July are the following which have been selected because of their possible interest to the electrical engineer. Unless otherwise specified, books listed have been presented gratis by the publishers. The Institute assumes no responsibility for statements made in the following outlines, information for which is taken from the preface or text of the book in question.

PLANNING FOR RESIDENTIAL DISTRICTS. Ed. by J. M. Gries and J. Ford. President's Conference on Home Building and Home Ownership, Washington, D. C., 1932. 227 p., illus., cloth, $1.00.—The final reports of 4 committees of the President's Conference on Home Building and Home Ownership; viz., city planning and zoning, subdivision layout, utilities for houses, and landscape planning and planting. This is a compact presentation of principles and practises, most interesting to planning commissions, public officials, civic improvement associations, and home owners. The various committees included well-known specialists in each field, and their findings are the result of wide experience.

REFRIGERATING DATA BOOK AND CATALOG. 1st ed., 1932–1933. Am. Soc. of Refrig. Engrs., N. Y., 1932. 480 p., 120 p., cat. information, illus., 10x6 in., leather, $3.50.—The basic data of refrigeration engineering are brought together in this volume which will be welcomed as a convenient encyclopedia of current practise. The various topics have been treated by specialists with the assistance of an advisory committee appointed by the society. Principles, equipment, and uses all are discussed.

STRESSES IN FRAMED STRUCTURES. Pt. 1. Design of Steel Mill Bldgs. By M. S. Ketchum. N. Y. & Lond., McGraw-Hill, 1932. 217 p., 9x6 in., cloth, $2.50.—This book covers the calculation of the stresses in simple beams, trusses, portals, the transverse bent and the 3-hinged arch, and is intended as a beginning course in the subject; 40 problems which cover the calculation of stresses in practically all types of simple roof and bridge trusses, bents and portals, are solved. Both algebraic and graphic methods of calculation are given. Reprinted from the author's "Design of Steel Mill Buildings."

SUPERHEAT ENGINEERING DATA. 7th rev. ed. N. Y. & Chic., Superheater Co., 1932. 253 p., illus., 7x5 in., leather, $1.00.—A useful collection of rules, formulas, numerical data, and other information frequently wanted by steam engineers and power plant operatives interested in superheating. In addition to the general data, the products of the publisher are described and their use illustrated by a variety of typical installations.

TEXTBOOK OF ELECTRICAL ENGINEERING, 1931. London, H. M. S. O., may be purchased in U.S. from British Library of Information, N. Y. 545 p., illus., 9x6 in., cloth, $2.88.—Prepared for engineer officers of the British army in its electrical service. The generation, transmission, distribution, and utilization of electricity are discussed in a thoroughly practical way, with special reference to the needs of military encampments, barracks, etc. The entire range of electrical work is covered in a severely practical manner. A book which seems well adapted for its purpose.

THEORY OF DIELECTRICS. By A. Schwaiger, transl. by R. W. Sorenson. N. Y., John Wiley & Sons, 1932. 480 p., illus., 9x6 in., cloth, $6.50.—This translation of the second edition of "Elektrische Festigkeitslehre" is intended to fill the needs of engineers and students in search of a comprehensive, readily understandable presentation of the laws of dielectrics. The book is divided into 3 parts, devoted to puncture, arcover, and the practical applications of high-voltage engineering. In addition to reviewing the work of others, considerable original work is included. Includes a list of references to other German publications.

UNIT PROCESSES AND PRINCIPLES OF CHEMICAL ENGINEERING. By J. C. Olsen. N. Y., D. Van Nostrand Co., 1932. 558 p., illus. 9x6 in., cloth, $5.00.—In preparing this textbook, the author has endeavored to present the fundamental chemical and physical principles determining the course of any given chemical reaction, the so-called unit processes which must be utilized in carrying it out upon a commercial scale, and the combination of these processes in proper sequence and coordination. The processes selected for treatment are the most important and most fully developed ones. Each chapter is by a specialist. An excellent introduction to chemical engineering.

WESTERN AND ATLANTIC R. R. OF THE STATE OF GEORGIA. Compiled by J. H. Johnston. Atlanta, Ga., Pub. Serv. Com., 1932. 364 p., illus., 9x6 in., leather, $5.00.—This volume traces the history of a state-owned railroad from its inception to the present day and describes its varying fortunes under state operation and in the hands of successive lessees. The volume is based upon official records and primarily is intended to supply legislators of Georgia with a convenient record of essential facts. It is also an interesting addition to the history of American railroads.

ALLGEMEINE UND TECHNISCHE ELEKTROMETALLURGIE. By R. Müller. Vienna, J. Springer, 1932. 580 p., illus., 9x6 in., cloth, 32.50 rm.—This work is to provide in one volume a concise yet thorough treatise on electrometallurgy and the electrochemical properties of metals, emphasizing commercial methods of production, but noting others briefly. Admirable as a good survey of current methods, with abundant references to literature and important patents.

ATM ARCHIV FÜR TECHNISCHES MESSEN. Lieferungen 4–12, Nov. 1931–June 1932. München und Berlin, R. Oldenbourg. Illus., 12x9 in., paper, 1.50 rm. each.—A compendium of measuring instruments and methods, intended to cover in 5 vols. the whole tech. measurement field. Parts issued monthly and sold singly, each with a 2- to 4-p. review of some dozen instruments or methods and giving ref. to orig. sources. Classified by the Decimal System and a special system, and arranged for loose-leaf binding.

AUSGEWÄHLTE SCHWEISSKONSTRUKTIONEN, Bd. 3. Rohrleitungs- und Behälterbau. By Holler and A. D. Fink. Berlin, VDI-Verlag, 1932. 88 p., illus., 12x9 in., cloth, 12.50 rm.—A set of 88 plates on the application of modern welding for container and pipe line construction. They present a wide variety of apparatus selected to show the advantages of welded equipment for chemical factories, steam plants, etc. Explanations in English.

ÉLECTRICITÉ ET MAGNÉTISME (MEMENTO D' ÉLECTROTECHNIQUE, v. 1). By A. Curchod. Paris, Dunod, 1932. 526 p., illus., 8x5 in., cloth, 99 frs.—Latest addition to handbooks on elec. engg. by the editor of "Revue Générale de l'Électricité," and written to provide the practising engr. with a concise and accurate ref. work similar to the well-known Am. and German handbooks. The first of 4 v., it discusses math., units, fundamental laws of electricity and magnetism, measurements and matls. Includes several bibliographies.

ELEKTRISCHE INDUSTRIEÖFEN FÜR WEITERVERARBEITUNG. By V. Paschkis. Berlin, J. Springer, 1932. 305 p., illus., 9x6 in., cloth, 31,50 rm.—Intended to present a systematic, comprehensive work on the elec. furnace to meet the needs of designers and users. The principles of design, methods of regulation, matls., and the economics of elec. furnaces are considered. Various constructions and their elements are treated at length. Limited to resistance furnaces, explicit directions for design being given.

ELEKTRISCHES KOCHEN. By F. Mörtzsch. Berlin, J. Springer, 1932. 178 p., illus., 10x7 in., cloth, 8.50 rm.—A report of semi-popular style, based upon a series of studies made by elec. plants and elec. mfrs. of Germany, to promote the genl. introduction of elec. cooking and wtr-htg. apparatus for homes, hotels, and institutions. Includes design of efficient apparatus and the finding of proper rates, therefor; also compares elec. heat with other kinds.

GRAPHS FOR ENGINEERS AND ARCHITECTS. By D. H. Lee. Lond., E. & F. N. Spon, Ltd.; N. Y., Spon & Chamberlain, 1932. 88 p., illus., 11x9 in., leath., $2.00.—These graphs treat of a variety of matters in building design and construction and are intended for quick design and checking of calculations. Those for determining safe loads on brick piers and steel, timber, and reinforced-concrete beams, stanchion stresses, wind stresses, panel loads, floor constructions, and similar problems are given and discussed.

INDUSTRIAL MANAGEMENT. By E. C. Robbins and F. E. Folts. N. Y. & Lond., McGraw-Hill, 1932. 757 p., illus., 9x6 in., cloth, $5.00.—Here the "case system" is applied to a beginner's course in industrial management, with 117 cases given to convey concepts underlying modern management; i. e., specialization, diversification, and integration; also their application to managerial control of raw materials, labor, plant, and equipment. To train the student to realize significant facts in managerial problems and to use them basically.

INTRODUCTORY COURSE IN PHYSICAL CHEMISTRY. By W. H. Rodebush and E. K. Rodebush. N. Y., D. Van Nostrand Co., 1932. 421 p., illus., 9x6 in., cloth, $3.75.—A textbook based upon a Univ. of Ill. course; for college Juniors with training in chemistry, physics, and calculus. Fundamental principles are given in a clear, precise manner. The course is designed for a year and presents the material usually included in such courses but with some novel methods and arrangement.

PHYSIKALISCHES HANDWÖRTERBUCH. By A. Berliner and K. Scheel. 2 ed. Berlin, J. Springer, 1932. 1428 p., illus., 11x8 in., paper, 96 rm.—Besides defining terms and concepts of classic and modern physics, this book gives much on astronomy, mathematics, geodesy, geology, physical chemistry, engineering, and other related subjects. It is encyclopedic, with articles signed, and frequent ref. to other information given. Invaluable, especially for those not versed in physics, and for physicists desiring quick orientation in subjects outside their field. The new edition is half again as large as the former.

PRINCIPLES OF REFRIGERATION. By W. H. Motz. 3 ed. Chicago, Nickerson & Collins Co., 1932. 1019 p., illus., 9x6 in., cloth, $7.50.—Giving fundamentals in the operation of refrigerating machinery; the properties of the usual media; design, construction, and operation of the apparatus; also important applications of refrigeration set forth practically and non-mathematically. Adopted by the Natl. Assn. of Practical Refrigeration Engrs. for its national lecture courses. Rewritten and considerably enlarged.

RECENT ADVANCES IN TOWN PLANNING. By T. Adams and others. N. Y., Macmillan Co., 1932. 400 p., illus., 10x7 in., cloth, 25s.—Describing recent advances and tendencies in town planning in its 3 phases of law, practise, and design in an effort toward a comprehensive survey. The point of view is British in its aspect with conditions in Great Britain given special consideration. There is, however, much upon conditions in America and other countries. A book of interest to American town planners. A useful bibliography of books and reports is included.

TEXTBOOK OF METALLURGICAL PROBLEMS. By A. Butts. N. Y. and Lond., McGraw-Hill, 1932. 425 p., illus., 9x6 in., cloth, $4.00.—Resembling "Metallurgical Calculations" by the late Prof. J. W. Richards and somewhat supplementing it, this book extends facts into certain channels also giving new and more accurate numerical data. Its main purpose is to supply a textbook with a graded treatment of the subject, suited for use in engineering courses rather than a handbook for practising engineers. A thorough introduction to problems arising in metallurgy and methods of solving them.

THOMAS' REGISTER OF AMERICAN MANUFACTURERS. 22nd ed., 1931–32. N. Y., Thomas Pub. Co., illus., 12x9 in., cloth, $15.00.—Listing, under products and firm names, Am. mfrs. and primary sources of supply. Trade names, brands, banks, boards of trade, and other commercial organizations, and trade papers are listed. Unequalled in comprehensiveness and completeness.

**Engineering Societies Library**

29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

# Officers and Committees for 1932-33

### President

| | |
|---|---|
| H. P. CHARLESWORTH | New York, N. Y. |
| | *(Term expires July 31, 1933)* |

### Junior Past-Presidents

| | |
|---|---|
| W. S. LEE | Charlotte, N. C. |
| | *(Term expires July 31, 1933)* |
| C. E. SKINNER | East Pittsburgh, Pa. |
| | *(Term expires July 31, 1934)* |

### Vice-Presidents

| Dist. No. | | |
|---|---|---|
| (2) | W. B. KOUWENHOVEN | Baltimore, Md. |
| (4) | W. E. FREEMAN | Lexington, Ky. |
| (6) | P. H. PATTON | Omaha, Neb. |
| (8) | A. W. COPLEY | San Francisco, Calif. |
| (10) | L. B. CHUBBUCK | Hamilton, Ont. |
| | | *(Terms expire July 31, 1933)* |
| (1) | J. ALLEN JOHNSON | Buffalo, N. Y. |
| (3) | E. B. MEYER | Newark, N. J. |
| (5) | K. A. AUTY | Chicago, Ill. |
| (7) | G. A. MILLS | Lansing, Mich. |
| (9) | C. R. HIGSON | Salt Lake City, Utah |
| | | *(Terms expire July 31, 1934)* |

### Directors

| | |
|---|---|
| J. E. KEARNS | Chicago, Ill. |
| F. W. PEEK, JR. | Pittsfield, Mass. |
| C. E. STEPHENS | New York, N. Y. |
| | *(Terms expire July 31, 1933)* |
| A. B. COOPER | Toronto, Ont. |
| A. E. KNOWLTON | New York, N. Y. |
| R. H. TAPSCOTT | New York, N. Y. |
| | *(Terms expire July 31, 1934)* |
| L. W. CHUBB | East Pittsburgh, Pa. |
| B. D. HULL | Dallas, Tex. |
| H. R. WOODROW | Brooklyn, N. Y. |
| | *(Terms expire July 31, 1935)* |
| G. A. KOSITZKY | Cleveland, Ohio |
| A. H. LOVELL | Ann Arbor, Mich. |
| A. C. STEVENS | Schenectady, N. Y. |
| | *(Terms expire July 31, 1936)* |

### National Treasurer

| | |
|---|---|
| W. I. SLICHTER | New York, N. Y. |
| | *(Term expires July 31, 1933)* |

### Acting National Secretary

| | |
|---|---|
| H. H. HENLINE | New York, N. Y. |
| | *(Term expires July 31, 1933)* |

### General Counsel

Parker & Aaron
20 Exchange Place, New York, N. Y.

### Local Honorary Secretaries

T. J. Fleming, Calle B. Mitre 519, Buenos Aires, Argentina.
V. J. F. Brain, Dept. of Pub. Wks., Phillip St., Sydney, N. S. W., Australia.
F. M. Servos, Rio de Janeiro Tramways Lt. & Pr. Co., Rio de Janeiro, Brazil.
A. P. M. Fleming, Metropolitan Vickers Elec. Co., Trafford Park, Manchester, England.
A. S. Garfield, 173 Blvd. Haussmann, Paris (8e) France.
Renzo Norsa, Via Caravaggio 1, Milano 25, Italy.
P. H. Powell, Canterbury College, Christchurch, New Zealand.
M. A. Chatelain, Polytechnical Institute, Apt. 27, Leningrad, Sosnowka 1-3, U.S.S.R.
A. F. Enstrom, Ingeniorsvetenskapsakademien, Stockholm, 5, Sweden.
W. Elsdon-Dew, P. O. Box 4563, Johannesburg, Transvaal, Africa.

## GENERAL COMMITTEES

### Executive

H. P. Charlesworth, Chm., 463 West Street, New York, N. Y.
J. Allen Johnson
C. E. Skinner
E. B. Meyer
W. I. Slichter
F. W. Peek, Jr.
C. E. Stephens

### Constitution and By-Laws

W. S. Gorsuch, Chm., 600 West 59th Street, New York, N. Y.
C. O. Bickelhaupt
E. B. Meyer
H. A. Kidder
W. I. Slichter

### Board of Examiners

H. Goodwin, Jr., Chm., Room 601, 133 South 12th Street, Philadelphia, Pa.
H. E. Farrer, Secy., 33 W. 39th St., New York, N. Y.
H. A. Currie
R. H. Marriott
H. W. Drake
L. W. W. Morrow
S. P. Grace
A. L. Powell
H. A. Kidder
W. R. Smith
F. V. Magalhaes
R. H. Tapscott
S. D. Sprong

### Columbia University Scholarships

W. I. Slichter, Chm., Columbia University, New York, N. Y.
Francis Blossom
H. C. Carpenter

### Coordination of Institute Activities

E. B. Meyer, Chm., 80 Park Place, Newark, N. J.
W. S. Gorsuch
H. H. Henline
W. H. Harrison
C. E. Stephens
E. S. Lee

### Economic Status of the Engineer

C. O. Bickelhaupt, Chm., Am. Tel. & Tel. Co., 195 Broadway, New York, N. Y.
W. S. Lee
W. S. Rugg
E. W. Rice, Jr.
C. F. Scott

### Edison Medal

*Appointed by the President for term of 5 years.*

D. C. Jackson, Chm.
C. F. Harding
F. A. Scheffler
*(Terms expire July 31, 1933)*

L. W. W. Morrow
W. S. Rugg
R. F. Schuchardt
*(Terms expire July 31, 1934)*

C. I. Burkholder
F. A. Gaby
H. J. Ryan
*(Terms expire July 31, 1935)*

H. H. Barnes, Jr.
E. B. Meyer
P. H. Thomas
*(Terms expire July 31, 1936)*

Gano Dunn
S. P. Grace
C. E. Stephens
*(Terms expire July 31, 1937)*

*Appointed by the board of directors from its own membership for term of 2 years*

J. E. Kearns
W. S. Lee
F. W. Peek, Jr.
*(Terms expire July 31, 1933)*

J. Allen Johnson
A. E. Knowlton
R. H. Tapscott
*(Terms expire July 31, 1934)*

*Ex-officio*

H. P. Charlesworth, President
W. I. Slichter, National Treasurer
H. H. Henline, Acting National Secretary
*(Terms expire July 31, 1933)*

### Finance

C. E. Stephens, Chm., Westinghouse Elec. & Mfg. Co., 150 Broadway, New York, N. Y.
E. B. Meyer
R. H. Tapscott

### Headquarters

R. H. Tapscott, Chm., 4 Irving Place, New York, N. Y.
H. H. Henline
C. E. Stephens

### Iwadare Foundation

F. B. Jewett, Chm., 195 Broadway, New York, N. Y.
W. I. Slichter
Gerard Swope

### Lamme Medal

R. D. Mershon
J. C. Smith
P. H. Thomas
*(Terms expire July 31, 1933)*

A. M. Dudley
P. M. Lincoln
J. C. Parker
*(Terms expire July 31, 1934)*

P. L. Alger
H. B. Gear
C. E. Skinner, Chm.
*(Terms expire July 31, 1935)*

### Legislaton Affecting the Engg. Profession

H. A. Kidder, Chm., 600 W. 59th Street, New York, N. Y.
James P. Alexander
J. C. Parker
T. F. Barton
J. R. Price
B. M. Brigman
Herbert S. Sands
W. H. Harrison
M. R. Scharff
L. F. Leurey
H. H. Schoolfield
L. W. W. Morrow
J. B. Thomas
W. I. Slichter

### Membership

R. L. Kirk, Chm., Duquesne Lt. Co., Pittsburgh, Pa.
E. P. Coles
C. H. Kline
F. G. Graf
J. A. Koontz
James Harrison
T. G. Le Clair
Joseph Hellenthal
W. G. Rubel
J. Allen Johnson
E. M. Wood
I. M. Stein

*Ex-officio:*

Chairmen of Section membership committees.

### N. Y. Museum of Science and Industry, Adv. Com. to

J. P. Jackson, Chm., New York Edison Co., 130 E. 15th St., New York, N. Y.
C. O. Bickelhaupt
R. H. Nexsen

### Popular Science Award

F. W. Peek, Jr., Chm., Genl. Elec. Co., Pittsfield, Mass.
W. H. Harrison
C. E. Stephens

### Principles of Professional Conduct, Code of

R. F. Schuchardt, Chm., 72 West Adams Street, Chicago, Ill.
A. H. Babcock
W. E. Mitchell
G. Faccioli
C. E. Stephens
F. B. Jewett
J. B. Whitehead

### Prizes, Award of Institute

W. H. Harrison, Chm., Am. Tel. & Tel. Co., 195 Broadway, New York, N. Y.
E. B. Meyer
Chester W. Rice

### Public Policy

Bancroft Gherardi, Chm., 195 Broadway, New York, N. Y.
C. C. Chesney
Farley Osgood
F. B. Jewett
R. F. Schuchardt
W. S. Lee
C. E. Skinner

### Publication

E. B. Meyer, Chm., 80 Park Place, Newark, N. J.
F. A. Lewis, Secy., 33 W. 39th St., New York, N. Y.
W. S. Gorsuch
H. H. Henline
W. H. Harrison
H. R. Woodrow

### Safety Codes

F. V. Magalhaes, Chm., Hopewell, N. J.
J. C. Balsbaugh
M. G. Lloyd
A. W. Berresford
Wills Maclachlan
L. B. Chubbuck
J. D. Noyes
J. F. Fairman
F. A. Pattison
H. B. Gear
Frank Thornton
F. D. Knight
H. S. Warren

### Sections

Everett S. Lee, Chm., Genl. Elec. Co., Schenectady.
W. B. Kouwenhoven
J. J. Shoemaker
G. H. Quermann
W. H. Timbie
I. M. Stein

*Ex-officio:*

Chairmen of all Sections of the Institute.

### Standards

A. M. MacCutcheon, Chm., 1088 Ivanhoe Road, Cleveland, Ohio.
H. E. Farrer, Secy., 33 W. 39th St., New York, N. Y.
A. B. Cooper
V. M. Montsinger
J. E. Goodale
F. D. Newbury
C. R. Harte
E. B. Paxton
J. F. Meyer
W. I. Slichter

*Ex-officio:*

Chairmen of working committees.
Chairmen of A.I.E.E. delegations and representatives on other standardizing bodies.
President of U.S. national committee of I.E.C.

### Student Branches

W. H. Timbie, Chm., Massachusetts Institute of Technology, Cambridge, Mass.
W. E. Freeman
C. F. Scott
F. O. McMillan
W. J. Seeley

*Ex-officio:*

All Student Branch Counselors.

### Technical Program

W. H. Harrison, Chm., Am. Tel. & Tel. Co., 195 Broadway, New York, N. Y.
C. S. Rich, Secy., 33 W. 39th St., New York, N. Y.
J. W. Barker
B. D. Hull
H. S. Bennion
W. B. Kouwenhoven
H. B. Gear
Paul MacGahan
W. S. Gorsuch
T. A. Worcester

*Ex-officio:*

Chairman of committee on coordination of Institute activities
Chairmen of technical committees.

### Transfers

E. B. Meyer, Chm., 80 Park Place, Newark, N. J.
H. Goodwin, Jr.
J. Allen Johnson
C. F. Scott

## TECHNICAL COMMITTEES

### Automatic Stations

D. W. Taylor, Chm., United Engineers & Constructors, Inc., 80 Park Place, Newark, N. J.

F. F. Ambuhl
A. E. Anderson
L. D. Bale
C. F. Craig
John Fies
A. M. Garrett
J. S. Hagan
Joseph Hellenthal
C. R. Higson
I. E. Moultrop
M. E. Reagan
O. J. Rotty
Garland Stamper
L. J. Turley
F. Zogbaum

### Communication

H. S. Osborne, Chm., 195 Broadway, New York, N. Y.

H. M. Bascom
W. H. Capen
A. A. Clokey
J. O'R. Coleman
C. F. Craig
R. D. Evans
W. L. Everitt
I. C. Forshee
C. M. Jansky, Jr.
T. Johnson, Jr.
G. M. Keenan
G. A. Kositzky
C. J. Larsen
J. R. MacGregor
John Mills
J. W. Milnor
C. W. Mitchell
E. J. O'Connell
P. H. Patton
F. H. Pumphrey
F. A. Raymond
H. A. Shepard
E. R. Shute
A. L. Stadermann
C. H. Taylor
H. M. Turner
F. A. Wolff

### Education

R. E. Doherty, Chm., Dunham Laboratory, Yale University, New Haven, Conn.

J. W. Barker
Edward Bennett
P. S. Biegler
H. V. Carpenter
C. S. Coler
G. R. Dooley
H. E. Dyche
O. W. Eshbach
O. J. Ferguson
H. H. Henline
D. C. Jackson, Jr.
C. L. Kinsloe
A. H. Lovell
R. C. Muir
H. W. Price
W. T. Ryan
Burke Smith
A. C. Stevens
G. B. Thomas
W. H. Timbie
W. E. Wickenden

### Electric Welding

K. L. Hansen, Chm., 2916 North Prospect Ave., Milwaukee, Wis.

C. A. Adams
J. H. Blankenbuehler
A. M. Candy
Alex Churchward
F. Creedy
S. Dushman
D. D. Ewing
H. M. Hobart
R. G. Hudson
J. E. Kearns
J. C. Lincoln
Ernest Lunn
F. C. Owen
C. L. Pfeiffer
J. Slepian
Wm. Spraragen
H. E. Stoddard
H. W. Tobey
G. H. Winkler

### Electrical Machinery

S. L. Henderson, Chm., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

P. L. Alger
B. L. Barns
E. S. Bundy
H. E. Edgerton
J. E. Goodale
T. T. Hambleton
J. L. Hamilton
A. L. Harding
C. F. Harding
E. W. Henderson
L. F. Hickernell
J. Allen Johnson
J. J. Linebaugh
H. C. Louis
W. V. Lyon
A. M. MacCutcheon
O. K. Marti
V. M. Montsinger
R. W. Owens
R. H. Park
E. B. Paxton
H. V. Putman
K. A. Reed
O. E. Shirley
R. G. Warner
C. A. M. Weber

### Electrochemistry and Electrometallurgy

Warren C. Kalb, Chm., National Carbon Co., Cleveland, Ohio

Lawrence Addicks
P. H. Brace
L. W. Chubb
Farley G. Clark
S. K. Colby
G. W. Elmen
J. C. Hale
W. E. Holland
F. A. Lidbury
R. G. Mansfield
K. L. Scott
H. Speight
N. R. Stansel
Magnus Unger
H. B. Vidal
G. W. Vinal
J. B. Whitehead
J. L. Woodbridge
C. D. Woodward

### Instruments and Measurements

E. J. Rutan, Chm., New York Edison Company, 92 Vandam St., New York, N. Y.

H. S. Baker
R. D. Bean
O. J. Bliss
P. A. Borden
H. B. Brooks
A. L. Cook
E. D. Doyle
W. W. Eberhardt
Marion Eppley
W. N. Goodwin, Jr.
I. F. Kinnard
O. A. Knopp
A. E. Knowlton
H. C. Koenig
W. B. Kouwenhoven
F. A. Laws
E. S. Lee
J. B. Lunsford
Paul MacGahan
R. T. Pierce
W. J. Shackelton
H. L. Thomson
H. M. Turner

### Electrophysics

V. Bush, Chm., Massachusetts Institute of Technology, Cambridge, Mass.

O. E. Buckley
W. G. Cady
W. F. Davidson
C. S. Gordon
L. O. Grondahl
W. B. Kouwenhoven
G. M. J. Mackay
S. S. Mackeown
H. Nyquist
J. Slepian
J. A. Stratton
W. C. White

*Liaison representatives of American Physical Soc.:*

Leigh Page
W. F. G. Swann

### Iron and Steel Production, Applications to

F. O. Schnure, Chm., Bethlehem Steel Co., Sparrows Point, Md.

K. A. Auty
J. J. Booth
F. B. Crosby
Wray Dudley
A. M. MacCutcheon
A. J. Standing
G. E. Stoltz
Wilfred Sykes
H. A. Winne
R. H. Wright

### Light, Production and Application of

W. T. Blackwell, Chm., 80 Park Place, Newark, N. J.

J. W. Barker
H. S. Broadbent
J. M. Bryant
E. C. Crittenden
W. T. Dempsey
E. E. Dorting
L. A. Hawkins
H. H. Higbie
H. E. Ives
W. C. Kalb
C. L. Kinsloe
R. D. Mailey
G. S. Merrill
P. S. Millar
P. H. Moon
R. E. Simpson
C. J. Stahl
C. E. Stephens
G. H. Stickney

### Marine Work, Applications to

R. A. Beekman, Chm., Genl. Elec. Co., Schenectady, N. Y.

E. C. Alger
H. C. Coleman
E. M. Glasgow
H. F. Harvey, Jr.
C. J. Henschel
Wm. Hetherington, Jr.
H. L. Hibbard
J. E. Kearns
A. Kennedy, Jr.
J. B. Lunsford
I. H. Osborne
G. A. Pierce
W. H. Reed
H. M. Southgate
W. E. Thau
A. E. Waller
O. A. Wilde
J. L. Wilson
R. L. Witham
W. N. Zippler

### Mining Work, Applications to

D. E. Renshaw, Chm., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

Graham Bright
J. H. Edwards
L. C. Ilsley
L. H. James
J. E. Kearns
Carl Lee
W. H. Lesser
C. W. Parkhurst
F. L. Stone
E. B. Wagner
J. F. Wiggert
C. D. Woodward

### Power Generation

J. R. Baker, Chm., 1611 Lexington Building, Baltimore, Md.

F. A. Allner
F. A. Annett
A. E. Bauhan
J. B. Crane
J. H. Ferry
N. E. Funk
W. S. Gorsuch
F. C. Hanker
J. P. Hogan
F. H. Hollister
A. H. Hull
D. C. Jackson
H. W. Leitch
A. H. Lovell
I. E. Moultrop
J. M. Oliver
A. L. Penniman, Jr.
G. G. Post
R. C. Powell
F. A. Scheffler
F. O. Schnure
R. E. B. Sharp
A. E. Silver
A. R. Smith
E. C. Stone

### Power Transmission and Distribution

P. H. Chase, Chm., Philadelphia Elec. Co., 900 Sansom St., Philadelphia, Pa.

R. N. Conwell, Vice-chm., 80 Park Place, Newark, N. J.

F. E. Andrews
G. M. Armbrust
H. W. Bibber
D. K. Blake
E. S. Bundy
A. B. Campbell
C. V. Christie
W. A. Curry
O. G. C. Dahl
A. E. Davison
R. D. Evans
F. M. Farmer
C. L. Fortescue
T. H. Haines
Edwin Hansson

## Geographical District Executive Committees

| District | Chairman (Vice-President, A.I.E.E.) | Secretary (District Secretary) |
|---|---|---|
| No. 1—North Eastern | J. Allen Johnson, 302 Electric Building, Buffalo, N. Y. | A. C. Stevens, General Electric Co., Schenectady, N. Y. |
| No. 2—Middle Eastern | W. B. Kouwenhoven, Johns Hopkins University, Baltimore, Md. | G. S. Diehl, Pennsylvania Water & Power Co., 1611 Lexington Building, Baltimore, Md. |
| No. 3—New York City | E. B. Meyer, 80 Park Place, Newark, N. J. | C. R. Jones, Westinghouse E. & M. Co., 150 Broadway, New York, N. Y. |
| No. 4—Southern | W. E. Freeman, University of Kentucky, Lexington, Ky. | E. A. Bureau, University of Kentucky, Lexington, Ky. |
| No. 5—Great Lakes | K. A. Auty, Commonwealth Edison Co., 72 West Adams St., Chicago, Ill. | A. G. Dewars, No. States Pr. Co., 15 S. 15th St., Minneapolis, Minn. |
| No. 6—North Central | P. H. Patton, Northwestern Bell Tel. Co., Telephone Building, Omaha, Neb. | M. S. Coover, University of Colorado, Boulder, Colo. |
| No. 7—South West | G. A. Mills, Michigan Gas & Electric Co., Lansing, Mich. | R. W. Warner, University of Kansas, Lawrence, Kans. |
| No. 8—Pacific | A. W. Copley, Westinghouse Elec. & Mfg. Co., 1 Montgomery St., San Francisco, Calif. | C. E. Baugh, 245 Market St., San Francisco, Calif. |
| No. 9—North West | C. R. Higson, Utah Power & Light Co., Kearns Building, Salt Lake City, Utah | Paul Ransom, Utah Apex Mining Co., Bingham Canyon, Utah |
| No. 10—Canada | L. B. Chubbuck, Canadian Westinghouse Co., Hamilton, Ont. | W. L. Amos, Hydro-Elec. Pr. Comm., 190 University Ave., Toronto, Ont. |

Note: Each district executive committee includes the chairmen and secretaries of all Sections within the district and the chairman of the district committee on student activities.

At the time of going to press for this issue, the list of student officers was not sufficiently complete to include.

# Affiliated Student Society

Brown Engineering Society............Brown Univ., Providence R. I.

# Industrial Notes

**Westinghouse Employes Exceed Sales Quota.**—Final reports of the Westinghouse Employes' sales campaign show a sales total of more than $2,900,000. Every employe was to sell at least one appliance. This average was beaten more than 50 per cent and the volunteers closed over 80 per cent of their prospects.

**Electrotrim Appointments.**—Announcement has been made by Electrotrim, Inc., Union City, Ind., manufacturers of the newly approved and labeled Electrotrim line of two-wire, non-metallic extension wiring, of the appointment of James S. Mahan as sales manager, and L. E. Fuller as special field representative. Both Mr. Mahan and Mr. Fuller were previously associated with Steel and Tubes, Inc.

**New Resistor Company.**—The Atlas Resistor Company, specializing in the manufacture of pack-wound tubular resistors, has been formed with headquarters at 423 Broome St., New York. W. A. Merrill, general manager of the organization, was previously associated with F. A. D. Andrea, Inc., and the Polymet Manufacturing Co. W. John Killoch, formerly of the David Killoch Co., is sales manager.

**Potential Transformers.**—The Allis-Chalmers Mfg. Co., Milwaukee, announces a new line of indoor, oil filled potential transformers, designated type PO, rated 200 va capacity, suitable for accurate metering service or for tripping or relay voltage supply. These are available for 6,900, 11,500 and 13,800 volt service, 60 or 25 cycles and the features of the new line are described as: high safety factor in insulation strength in the primary winding; liberal sized primary porcelain; internal parts cover suspended, facilitating inspection; fixed secondary terminals inclosed in conduit terminal compartment.

**New Power Reduction Unit.**—The Merkle-Korff Gear Co., Chicago, is producing a small, low priced power reduction unit with a wide range of applications due to its compactness and extreme flexibility. The gears run in grease which is sealed in, insuring positive lubrication and quiet operation. The unit can be supplied in any speed from a motor speed of 3,000 rpm down, either for clock-wise or reverse rotation. The unit is so constructed as to be easily attached to any device or mechanism. Induction or synchronous type motors are used.

**Pocket Foot-Candle Meter.**—According to the manufacturer, many simplified and new photocell applications with relays and indicating instruments have been made possible through the new Weston Photronic photoelectric cell. The latest of these applications, by the Weston Electrical Instrument Corporation, Newark, N. J., is a pocket size foot-candle meter built especially for salesman's use, calibrated to read directly on three ranges—50, 250, or 500 foot-candles. One cell is used as an adjustable light collector, with readings appearing on a scale 2.36 inches in length. The cell and instrument are housed in a neat, black, moulded case, measuring approximately $3^{3}/_{8}$ x 7 x $2^{1}/_{4}$ inches.

**Oilproof Portable Cable.**—In certain types of service, portable cords are subjected to the continual attack of oil resulting in deterioration not only of the outer coverings, but eventually of the insulation. To meet this condition the Okonite Company, of Passaic, N. J., has developed a full line of portable cords and cables having a special outer sheath which is impervious to the destructive acting of oil or grease. This line of cords and cables is called "Oilproof Okocord." As the name implies, the new cord possesses all the good qualities of the Okocord line, plus continued resistance to oil, thus rendering it highly suitable for use around machine shops, garages, refineries, oil wells, etc. Strong sunlight and ozone also have little effect on this cord.

**More Capacity for Cables.**—Load-carrying capacity of single-conductor lead-covered cable is increased and operating cost of the circuit is decreased by the use of a new split-type insulator which is so designed that it can be installed on a cable in service, without cutting the conductor. The insulator, a General Electric product, consists of two split alloy wiping sleeves and a split molded-compound insulator. The wiping sleeve halves are soldered together at the assembly, and bolted to the insulator. The joints between the wiping sleeve and the halves of the insulator are made permanently oil-tight and vacuum-tight by compressing oil-proof gaskets between the surfaces. When single-conductor cable is used on alternating-current systems, the current flowing in the conductor induces a voltage in the lead sheath. If the sheath forms a continuous circuit, this induced voltage causes current to flow in the sheath, resulting in sheath losses that produce a heating effect, which decreases the load-carrying capacity of the cable. Insertion of sheath insulators in the lead sheath largely reduces such currents and losses. In addition to the new split sheath insulators there are also ones to be placed in the casing of a joint or in the cable sheath at the end of a joint.

**Air Cooled Transformers.**—Bulletin 172, 2 pp., loose leaf. Describes Wagner types AA and AC units in sizes 1 to 50 kva, voltages 100 to 600. Applications are outlined. Wagner Electric Corp., 6400 Plymouth St. St. Louis, Mo.

**Relays.**—Bulletin, 4 pp. Describes "Diamond H" magnetrole relay, applicable in many standard and special applications. It is particularly adapted for motor and light control, time and temperature control, signal equipment, photo-electric cell operation, sign flasher service, etc. Hart Mfg. Co., Hartford, Conn.

**Electrolytic Condensers.**—Catalog 1-C, 16 pp. Describes electrolytic condensers, molded mica condensers. Solar Mfg. Co., 599 Broadway, New York.

**Air Cooled Transformers.**—Bulletin GEA 897B, 16 pp. Describes G-E air cooled transformers, types M and D, for reducing voltage, balancing voltage, boosting voltage, insulating circuits and phase changing. General Electric Co., Schenectady, N. Y.

**Lifting Magnets.**—Bulletin 900, 16 pp. Describes various types of EC & M lifting magnets and illustrates recent improvements made in these products. Photographs of the magnets in use by various industries are also shown. The Electric Controller & Mfg. Co., Cleveland, O.

**Welding Electrodes.**—Bulletin, 16 pp., entitled "Murex Heavy Mineral Coated Electrodes." Numerous applications of inorganic flux coated welding electrodes are described. The welding of mild steel and boiler plate, stainless steel alloys, manganese steel, high carbon steel, stainless iron, and the building up of railway rail ends, special manganese track work, as well as the repair of castings and heavy parts, is covered. Metal & Thermit Corp., 120 Broadway, New York.

**Industrial Rubber Goods.**—Condensed Catalog, 24 pp., entitled "Engineering Data, Industrial Rubber Goods," giving a simplified, comprehensive outline of the principal Goodrich rubber products for industrial purposes. Included are tables of rubber transmission belting showing horsepower capacities, minimum pulley diameters, leather belt equivalents and list prices. A table on conveyor belts makes it easy to figure the required sizes and plies of a conveyor belt without using a formula. Rubber hose of various types for industrial purposes is also described. The B. F. Goodrich Co., Akron, O.

**Horizontal Bearing Mountings.**—Bulletin S, 36 pp. Describes horizontal mountings, Kingsbury thrust bearings and journal bearings, small to medium sizes. These bearing mountings are widely used in high speed centrifugal pumps, horizontal hydroelectric units and similar services. The standard shaft sizes for these mountings vary from 2 in. up to 9 in. and the thrust bearing capacities from under 1,000 lbs to over 50,000 lbs. The bearings are automatically lubricated and may be water-cooled when necessary. They are suitable for speeds up to 3,600 rpm or more, as well as for lower speeds. Dimension lists and capacities of three types of mountings of combined thrust and journal bearings and similar data on mountings for individual journal bearings are included. Kingsbury Machine Works, Inc., 4324 Tackawanna St., Philadelphia, Pa.

A.I.E.E. Section and Branch activities continue to "take the Institute to the membership." About 80 per cent of all members now are located within Section territory. Cooperative relations between Sections and neighboring Branches have continued to receive much attention. *p. 738–40*

SUGGESTIONS for the nomination of 1933 A.I.E.E. officers must be received at Institute headquarters not later than November 15, 1932. *p. 736–7*

TO ASSIST engineering readers who are interested in economics and sociology, The Engineering Foundation has prepared a list of books and references covering a variety of subjects and views in these fields. *p. 745–6*

THERE is a need today for variety in technical education; the development of adult or evening instruction in metropolitan areas is said to offer a partial solution for meeting this need. *p. 698–1*

NOISE measurements are extremely helpful in the present day "war on noise"; such measurements are beginning to be used as a basis of acceptable "quietness," and provide the principal means of detecting noise sources. *p. 705–8*

SPECIALLY designed supporting towers were required to carry electric power transmission lines into the city of Milwaukee over railway right-of-way. *p. 708–11*

HARMFUL vibration in electric power transmission lines can be controlled effectively by properly installed Stockbridge dampers of suitable design. Difficulties experienced with early designs of this damper have been overcome by the use of a high strength steel supporting cable. *p. 696–7*

ABOUT 2,500 persons are estimated to suffer from electric shock annually in the United States; approximately half of that number suffer fatal injuries. Experimental work for determining effective remedial measures to reduce this toll are being continued. *p. 693–6*

DOUBLE conductor electric power transmission lines have about 20 per cent less reactance than single conductor lines having the same weight of conducting metal, but cost more. Formulas have been developed for calculating the electrical characteristics of such lines. *p. 701–4*

FROM the standpoint of interruption to customers, protection of electric power distribution systems from disturbances due to lightning is a problem of major importance. Operating experience shows that lightning arresters provide sufficient protection to justify their installation economically. *p. 716–27*

PIONEERING in the use of large capacity automatically adjustable blade turbines of the propeller type, the Safe Harbor hydroelectric development involved an unusual amount of experimental and engineering study. Limited experience with this type of turbine in this country led to the construction of a hydraulic laboratory for testing model turbines complete with scroll case and draft tube. *p. 728–33*

ATTENDANCE at the 1932 Pacific Coast convention concluded at Vancouver, B. C., on September 2, reached a total of 300 persons—a fitting tribute to the unremitting efforts of the committees in charge. The convention was featured by the usual high quality technical sessions, active student participation, interesting inspection trips, and delightful entertainment and sports events. *p. 734–6.* Some of the discussion presented at technical sessions has been summarized. *p. 737–8*

# 115-Kv Submarine Cable for Columbia River Crossing

**Outstanding among cable installations is the recently completed 115-kv oil filled submarine cable which crosses the Columbia River between the states of Washington and Oregon. Three single-conductor hollow-core 750,000-cir-mil cables having armor wires of hard drawn copper instead of steel, are laid directly on the bed of the river 4 ft apart, and cross 2 channels of the river, 3,460 and 1,360 ft in width. These crossings are connected by an overhead transmission line. A 33-ft maximum difference in the water level of the river necessitated the solution of a number of problems at this installation. The many interesting features are described in this article, which is divided into 4 main sections. The first section describes the general reasons for the principal decisions regarding the cable, the second describes the specifications and manufacture, the third describes the design of the field installation, and the fourth covers installation and construction methods. Each section contributes valuable information in its respective field.**

DELIVERY of electric energy from the new Ariel plant of the Inland Power & Light Company on the Lewis River, Wash., to the load center of the Northwestern Electric Company in Portland, Ore., made necessary the construction of approximately 36 miles of transmission line including a 115-kv submarine cable circuit crossing the Columbia River. The crossing site is just north of Portland city limits and about one mile west of Vancouver, Wash. The river, one of North America's largest streams, forms the boundary between the states of Oregon and Washington.

At the crossing location, shown in Figs. 1 and 2, the river is divided by the $^1/_2$-mile wide Hayden Island into 2 channels, the north channel being 3,460 ft in width and the south channel 1,360 ft. Two separate crossings, one across either channel, were therefore required. These were connected by an *H*-frame wood pole type transmission line as study had shown this to be more economical than to continue the cable underground across the island.

The selection of a nominal voltage of 110 kv for the transmission voltage was determined by an economic analysis of costs at various voltages for delivering energy from Ariel and other possible adjacent developments to load centers in the Portland area; also from consideration of interconnected operation with other utilities in the Northwest. This later consideration has a very important bearing upon the problem since all of the other major companies are now operating or contemplate conversion of principal trunk lines to nominal 110-kv operation. Furthermore, physical interconnections already exist between all of these companies and interconnected operation has been employed for several years past, so the economic advantages to be gained and necessity for planning to meet the increasing demands for interchange capacity have been clearly demonstrated.

For the construction program necessary to meet the load and service requirements, cost comparisons between crossing the river overhead or submarine clearly established the economy of the submarine method. Factors contributing to this were: the requirement of 198 ft minimum clearance above low water; the flat terrain at the crossing site or anywhere in the vicinity; the small increment of cost for a double circuit overhead crossing over a single circuit, making construction for 2 circuits the logical procedure although only one was needed initially; and the unusual requirements of mechanical strength for the overhead construction on account of the occasional very severe ice loading conditions experienced.

Very careful and thorough consideration was given to the idea of trenching of cables in the river bottom in order to provide protection from ship anchors and other forms of external damage. With present river depth at minus 28 ft el (low water at 0) it was decided that the trench would have to be excavated to minus 40 ft el in order to be beneath future ship channel

---

Full text of "115-Kv Submarine Crossing of the Columbia River" (No. 32-125) presented at the A.I.E.E. Middle Eastern District meeting, Baltimore, Md., Oct. 10–13, 1932.

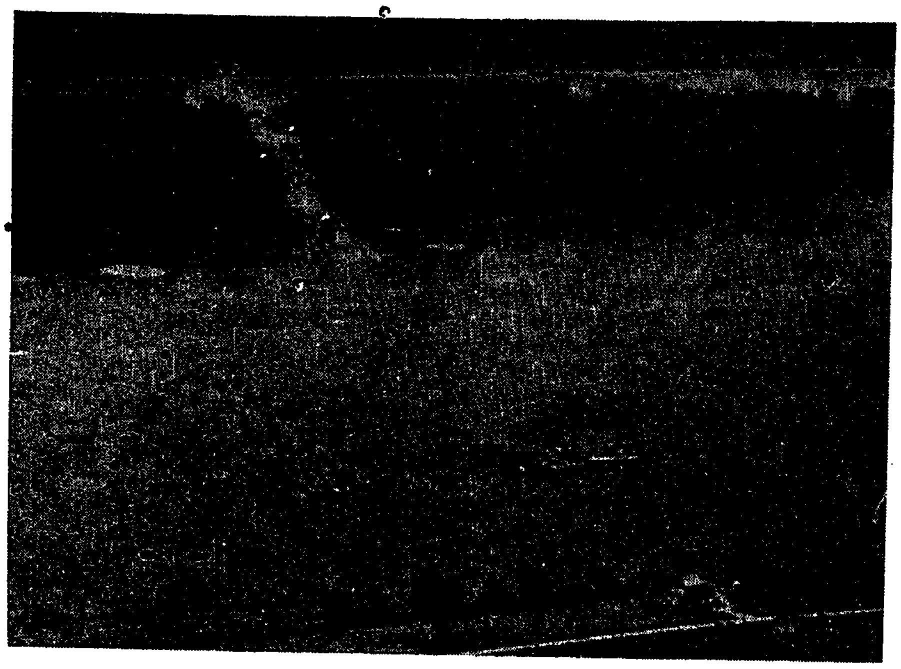

Fig. 1. Site of the 115-kv submarine cable crossing the Columbia River, viewed from the Washington side during construction

bed as well as out of reach of projecting anchor and dredge cutter heads. Such a trench constructed 7 ft wide on the bottom with walls of 1 : 3 slope for withstanding river current would cost from $40,000 to $50,000 and there would be no definite assurance that the trench at right angles to the current could be kept open during laying without additional expenditures for sheet piling or for removing extra sand yardage.

With the cables covered in a trench to minus 40 ft el it is believed that it would not be economically practical to salvage the cable in case defects developed. This fact would therefore necessitate the abandonment of that cable and the writing off of a comparatively large investment. With oil filled cable laid directly on the bed of the river it is believed that the cable can be lifted readily and repaired in case of fault developing. The Northwestern Electric Company has an experience record of 92 submarine cable years, covering 11 3-phase 11,000-volt submarine cables laid directly on the beds of the Columbia and Williamette Rivers in the general vicinity of the new crossing. This experience record, excluding pothead failures, discloses only one failure. In that case failure occurred when the cable was accidentally picked up by a sand digger clam shell. This favorable experience record, combined with greater accessibility and less chance of abandonment, together with fixed charge savings of from $5,200 to $6,500 per yr were responsible for the decision to lay the cable directly on the bed of the river.

During the 3-yr study of this problem considerable time was devoted to consideration of the relative merits of cable with solid type of insulation versus oil filled type. The experience and advice of high voltage cable specialists in several manufacturing and utility organizations throughout the United States was sought. Final decision to specify oil filled cable was based on the following facts:

1. Most favorable operating records of oil filled cable over the past 4 yr, particularly when compared with solid type cable operating at high voltage.
2. High electrical endurance strength of oil filled cable as demonstrated in laboratory and field tests.
3. Ability of oil filled cable to maintain perfect impregnation and prevent void formation and ionization.
4. Development of a satisfactory joint for oil filled type submarine cable.

Three cables were laid directly on the bed of the river 4 ft apart and the shore ends above extreme low water were trenched in and covered with 4 ft of sand. Some slack in the shore ends was provided for use in case of channel changes by the scouring action of the river or by dredging operations.

## Design and Manufacture of the Columbia River Cable

THE hollow core, single conductor, oil filled cable for the 115-kv submarine crossing of the Columbia River has the following specifications and calculated dimensions:

Inside diam of copper supporting spiral, 0.690 in.
Inside diam of conductor strands, 0.790 in.
Outside diam of conductor strands, 1.277 in.
Conductor cross section, 750,000 cir mils.
Thickness of wood pulp paper insulation, 0.560 in. (nominal).
Perforated copper shielding tape (0.005 in.) interlocked with one paper tape.
Inside diam of lead sheath, 2.497 in.
Outside diam of lead sheath, 2.810 in.
Lead sheath $^5/_{32}$ in. 2 per cent tin-lead alloy.
Two layers 16/3 ply tarred jute and asphalt.
Hard drawn copper wire armor (0.238 in. diam).
One layer 16/3 ply tarred jute, asphalt, and whiting.
Overall diam, 3.80 in.
Weight, 20 lb per ft.
Voltage rating, 115 kv, 3 phase, grounded neutral.

Seven reel lengths were manufactured and each length included not only the amount required for installation but also additional cable for test purposes. As manufactured, 3 lengths were approximately 3,780 ft each, 3 more were approximately 1,600 ft and the remaining 832-ft length was shipped on a separate reel to be held in reserve for possible future emergency repair work.

The lead sheath was applied before drying and impregnation treatment. Each length was placed in a steam chamber. Vacuum was applied at each end of the hollow core and drying continued until all moisture was removed. Due to the long lengths involved this drying treatment was necessarily slow, the 3,780 ft lengths requiring 391 hr. After drying impregnation was completed with carefully selected degasified oil having the following characteristics:

Specific gravity, 0.91
Viscosity at 37.8 deg C, 100 (Saybolt)
Pour point, −40 deg C

Following the usual practise, the oil in the core, after impregnation was completed, was continuously maintained under positive pressure by use of one or more cell type pressure reservoir units connected to the cable end. The first principle of oil filled cable practise is to always maintain positive oil pressure at all points of cable length in the factory and during shipment, installation, and operation. The various operations that are closely followed throughout are solely for the purpose of initially removing air, moisture, and other impurities from the entire system, completely filling with oil and maintaining positive oil pressure, so that additional impurities cannot enter through accidental leaks.

After impregnation the cable lengths were subjected to a special volumetric pressure test for assurance that all air and other gases had been removed. The complete lengths or test samples cut from the ends were then subjected to various special and standard acceptance tests, chief among which were the following:

1. Factory reel high potential test, 166,000 volts conductor to sheath for 15 min at 60 cycles, before armoring.

2. Dielectric power factor and ionization factor, 20 to 100 volts per mil, 60 cycles on each reel length before and after armoring. Ionization factor limit 0.2 per cent actual 0 per cent.

3. High voltage time test. Three 75 ft lengths, one before and 2 after armoring. 196,000 volts for 6 hr with 20 per cent voltage steps every 6 hr to failure. The samples failed at 235 kv in 2, 3, and 5 hr.

4. Two 25 ft samples before armoring for 60 cycle dielectric loss test. The average measured power factor was: 0.32 per cent at room temperature, 0.27 per cent at 60 deg C, 0.28 per cent at 70 deg C and 0.30 per cent at 80 deg C.

5. Three 15 ft samples, 2 before and 1 after armoring for bending test. Four cycles of 180° bending at −10 deg C around a mandril 12 times cable diameter. Physical condition noted but electrical tests omitted as meaningless.

After test the 7 shipping lengths were as follows: 3 lengths 3,717 ft each, 3 1,532 ft each, and 1 spare 832 ft length. Each was placed on a separate reel in the body of which was mounted a sufficient number of cell type pressure reservoir units to maintain an oil pressure between 5 lb and 15 lb during shipment and installation. All shipping reel bodies were 7 ft 2 in. wide. The 3 reels for 3,717 ft lengths were 11 ft 2 in. in diameter, and the remaining 4 had a diameter of 9 ft 6 in. Each reel was axially mounted in a permanent cradle with band brakes for unreeling cable. Due to excessive size and shipping weight $45^3/_4$ tons for 3,717 ft units and $21^1/_2$ tons for 1,532 ft units, it was necessary to use special gondola freight cars and load only one reel per car. Obviously, such excessive size and weight required special manufacturing facilities throughout and the various operations presented a very interesting and difficult problem.

## Carrying Capacity of Cable

The carrying capacity of a submarine cable, where the same size conductor is used throughout, is determined by the thermal conditions at the shore ends, the temperature rise of immersed section being, of course, much less. The carrying capacity of this particular installation was more difficult to determine than usual because of the relatively short vertical risers at the ends representing the limiting thermal conditions. Due to transfer of heat from these exposed vertical risers into the earth, the usual formulas for cable in air do not apply exactly and the thermal correction factor was checked by heat run after installation. On the basis of an ambient air temperature of 40.5 deg C, this cable has a conservative rating of 575 amp for maximum conductor temperature of 70 deg C at vertical risers and with copper armor bonded at base of terminals.

If steel armor had been used under the same conditions, the rating would have been only 430 amp, due to excessive armor and sheath losses. The advantages of low resistance copper armor in this respect are fully described in "Losses in Armored Single Conductor Lead Covered A-C Cables," by O. R. Schurig, H. P. Kuehni, and F. H. Buller, A.I.E.E. Transactions, v. 48, 1929, p. 417–34.

## Accessory Design and Manufacture

The following accessories and special installation and maintenance treating equipment were also furnished:

14 single conductor outdoor porcelain terminals or potheads.

6 6 gal and 8 10 gal gravity cell type oil feeding reservoirs.

4 10 gal cell type oil pressure reservoirs for maintaining pressure on emergency oil supply tanks at each terminal.

8 50 gal emergency oil supply tanks with oil level gages, nitrogen gas cylinders, valves, fittings, etc., connected 2 in parallel at each terminal.

800 gal special oil in 50 gal drums for filling terminal equipment after assembly.

4 valve panels (6 valves each) for emergency paralleling or interchange of oil feed for each phase.

2 repair joints with armor box and clamping rings.

Copper tubing, armored lead piping, valves and miscellaneous fittings for connecting oil system.

1 portable, motor driven oil degasifier.

1 portable, motor driven vacuum pump.

1 impregnating bottle.

Rubber vacuum hose, toggle clamps, tanks of specially dried carbon dioxide and miscellaneous fittings.

The outdoor potheads were rated at 132 kv, following the usual practise of using one size larger

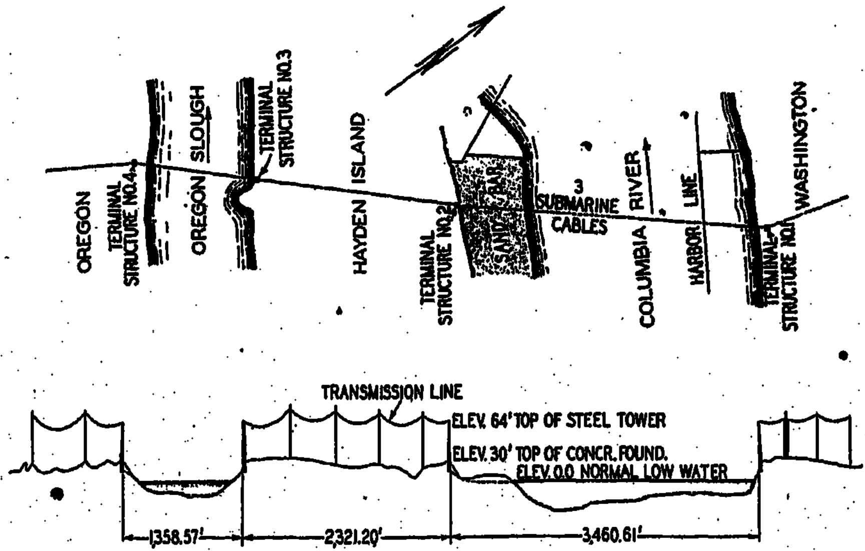

Fig. 2. Plan and profile of the 115-kv submarine cable crossing

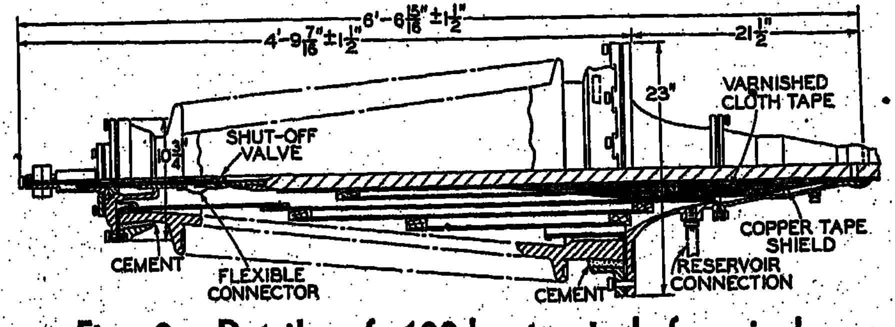

Fig. 3. Details of 132-kv terminal for single conductor oil filled cable

porcelain. A cross sectional drawing of this design is shown in Fig. 3. The guaranteed dry and wet 60 cycle flashover was 375 kv and 280 kv, respectively, and before shipment the potheads were subjected to the following test for leakage: 4 hr vacuum followed by 2 hr oil pressure at 80 deg C. The terminal lugs had a flexible type stud to allow limited movement of the cable conductor during expansion and contraction. There was also a special shut-off valve in the stud so that oil pressure could be maintained in the cable core while the terminal was being vacuum treated and filled with degasified oil after assembly.

All reservoir units, piping fittings, and other accessories were also subjected to rigid tests for leaks before shipment. They were again tested after installation and then carefully dried, evacuated, and filled with degasified oil. The cell type reservoir designs have been described in detail in "Characteristics of Oil Filled Cable," by G. B. Shanklin and F. H. Buller, A.I.E.E. Transactions, v. 50, 1931, p. 1, 411–20; and "Oil Pressure Reservoirs for Underground Cable," by T. C. Aitchison, *General Electric Review*, July 1931, p. 410–15. The first of these also gives a general outline of the principles of oil filled cable practise, and a complete bibliography.

## Design of Field Installation for the Columbia River Cable

THE 4 terminal structures of the 115-kv submarine cable crossing of the Columbia River consist of reinforced concrete bases and platforms supporting cable terminals and accessories, and steel dead end structures for the overhead lines. The details of the terminal structures are shown in Fig. 4.

The decks of these 4 structures are all at the same elevation and are above the usual high water level, but the lower portions will be submerged at high water. The deck of each structure is surrounded by a barrier of steel plate to protect the potheads and accessories from bullets of youthful sportsmen who frequent the neighborhood, and facing the water is a large sign warning against anchorage.

The structure on the Washington side of the main channel has a foundation of wooden piles. This structure is nearer to the water's edge than the others and is adjacent to the ship channel. No piles are used underneath the other structures. Jetties or dykes for protection against undercutting and damage by floating objects during flood periods will be provided for the structures on both sides of the main river channel when deemed necessary.

The steel dead end overhead structures are mounted on the decks of the concrete terminal structures. They are self-supporting and are designed to withstand the maximum expected strain under heavy ice loading of the 795,000 cir mil A.C.S.R. overhead conductors. To guard against failure from unforeseen loading conditions each conductor is dead-ended through a shearpin designed to fail at the value corresponding to the maximum safe strain on the structure.

### ANCHORING

Anchoring of the cables is accomplished by the use of 2 concrete dead-men at each terminal structure. Chains are carried back from these dead-men to the 3 cables. Attachment to the cables is made by means of basket grips, this attachment being considered sufficient due to the fact that a considerable section of cable between the structures and the water's edge is buried in the sandy river bank, which will take up a considerable amount of pulling tension.

### BONDING AND GROUNDING

Due to the fact that the cable armor is hard drawn copper some special problems were encountered in the bonding and grounding of this installation. During operation the armor carries a current almost as great as that in the conductor and for this reason carefully designed and installed high capacity bonds are necessary.

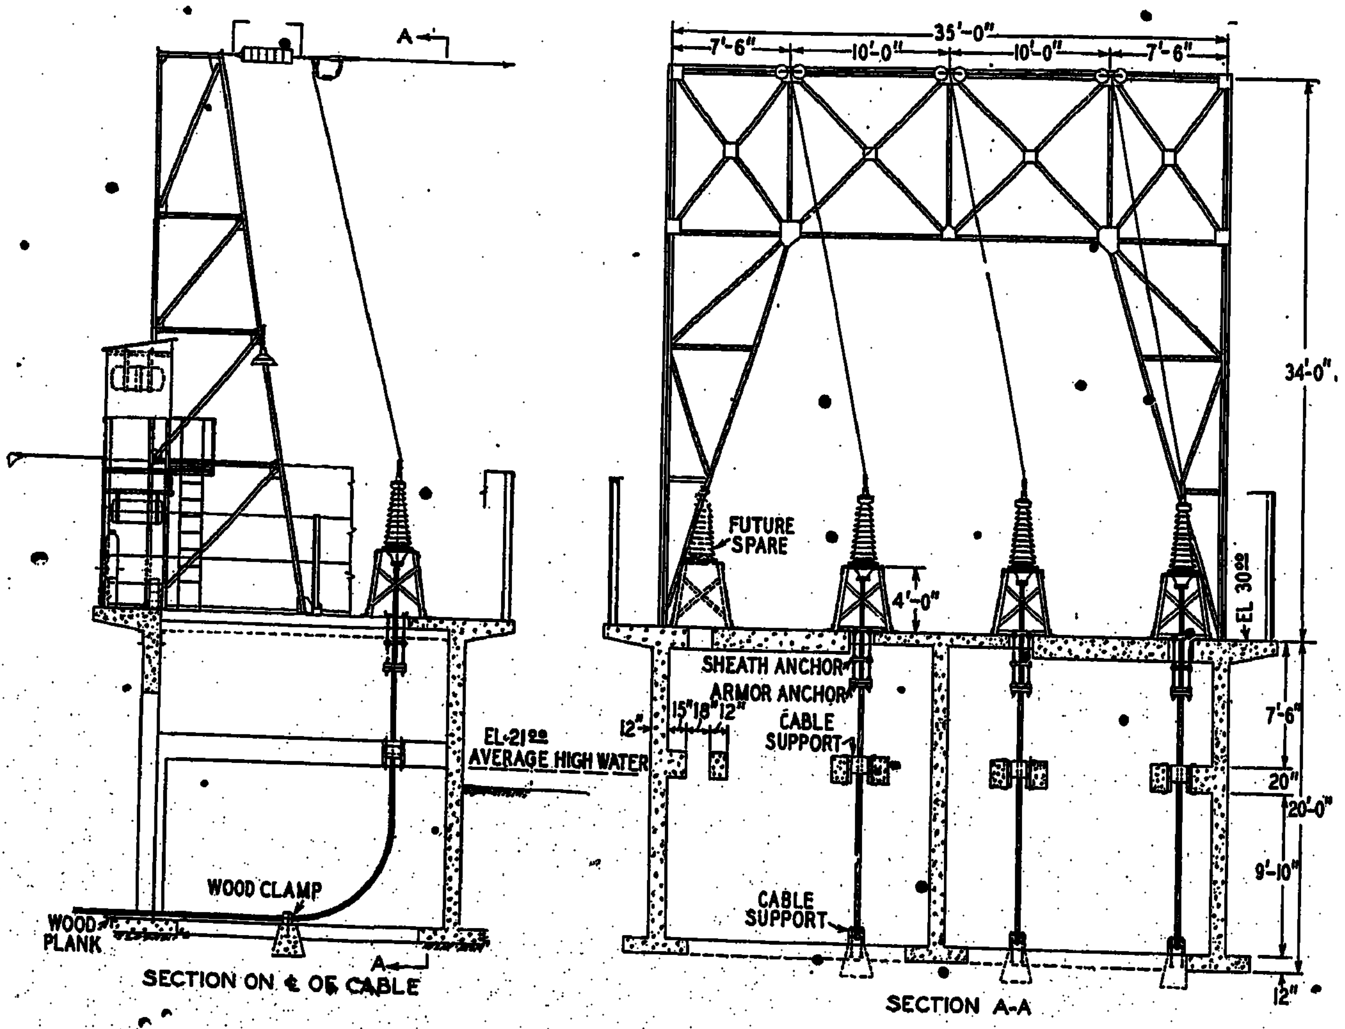

**Fig. 4. Outline of design for terminal structures. Structure No. 1 differs slightly, having a foundation of wooden piles**

Careful study of probable electrolysis conditions, including analysis of the river water, indicated that there should be very little corrosion due to electrolysis. The water has a comparatively high sulphate content. If electrolysis does have a tendency to start at any point, the lead sheath soon becomes coated with a tough, permanent film of lead sulphate, thus automatically stopping the action. However, since with copper armor any corrosion which might occur would affect the anodic lead sheath and not the armor, it was considered advisable to take all possible precautions against damage by corrosion. To this end the armor strands of the 3 cables are bonded together at each end separately from the sheaths, the latter also being bonded together separately and grounded. The 2 sets of bonds are connected together by a removable jumper, both armor and sheath being grounded when this jumper is in place. The idea of this arrangement is to permit periodically inserting an ammeter between the armor and sheath and testing for electrolysis currents. If appreciable currents should develop the sheath and the armor can then be separated by removing the jumper or they can be connected through a battery supplying a potential which is counter to the electrolysis potential.

Arrangement of the grounding system is shown in Fig. 5. The ground electrodes consist of a series of driven rods interconnected with each other and with all equipment and structures, forming a low resistance grounding network.

### Lightning Protection

The lightning protection for the cables and terminals consists of simple spillway gaps mounted across the dead end insulator strings at each terminal structure. They are well grounded to the grounding network which, in turn, provides a short and effective connection to the cable sheaths. The gap setting for operation at 115 kv is 30 in. between points, this being considerably below the impulse insulation strength of the cable and terminals and also somewhat below the maximum recommended setting of 36 in. given by the manufacturer of the cable and accessories. It is also somewhat higher than the maximum expected switching surge voltages, so that lightning should be the only cause for flashover. Flashover of these gaps may involve a trip-out of the transmission circuit in a manner similar to that of a lightning stroke occurring at any other point of the line.

On account of the fog and contamination condition existing along the river, a leakage distance of 80 in., equivalent to 1.2 in. per kv to ground, is provided on the terminal bushings. Two strings in yoke each of 7 suspension units giving leakage distance of approximately 90 in. are used on the dead ends. No pedestal insulators are required with the simple structure design employed.

### Oil Level Alarm System

Since the installation is somewhat remote from the nearest attended substation it was considered advisable to provide remote indication of oil level conditions in the oil reservoirs. Such indication is provided by alarm devices at the oil reservoirs, which devices are connected to telephone lines terminating in Vancouver substation. By a system of resistances individual indication of the different reservoirs can be given over a single telephone line from a given location, the indications being obtained by an ammeter type of indicator in the station. Only 3 of the structures are equipped with this signal system, namely, the 2 on the main channel and the 1 on the north side of Oregon Slough. Fig. 6 is a diagram of this signal system.

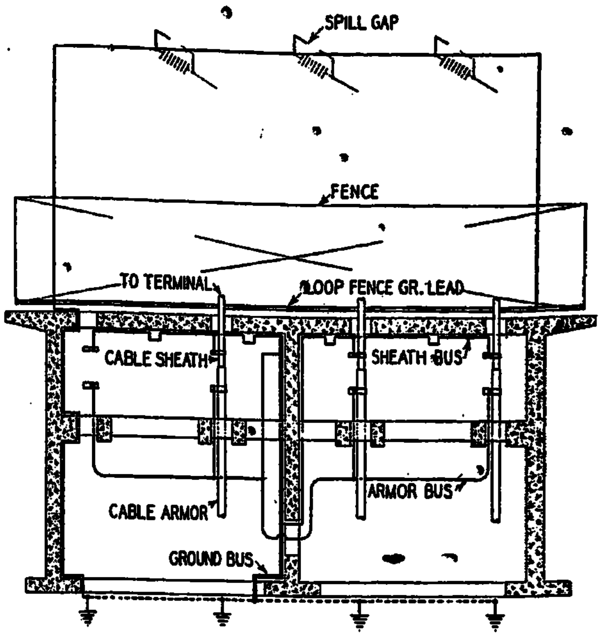

**Fig. 5. Bonding and jointing arrangements at terminal structures**

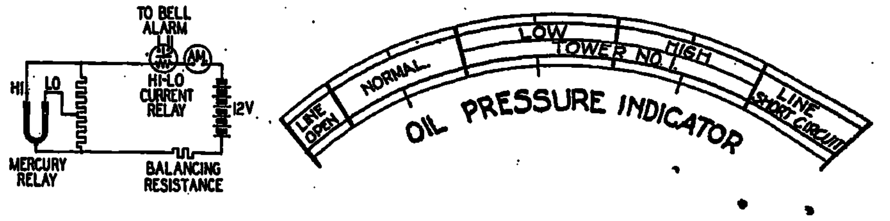

**Fig. 6. (Below) Oil pressure signal system and indicator ammeter scale**

### Emergency Oil Supply

In case of damage to the cable (as for instance by a ship's anchor) which results in an oil leak, considerable time must elapse before the cable can be raised and the damage repaired. It was therefore considered advisable to provide emergency oil storage so that continuous oil flow can be maintained until repairs are effected. This emergency storage consists of simple drum type reservoirs, 2 of 50 gal capacity each for each terminal structure, with suitable piping and valve arrangement to connect these reservoirs with the cable oil system when needed. The valves are hand operated. These reservoirs are provided with tanks of nitrogen under pressure not normally in contact with oil, but with valve arrangements by which the oil in the tanks can be displaced by the nitrogen under emergency conditions. The contact of nitrogen with the oil for short periods of time is not considered especially objectionable, although contact for longer periods of time would be definitely deleterious. The nitrogen is supplied in ordinary high pressure cylinders fitted with special reducing valves. Safety valves are provided to limit the pressure of the oil when forced by the nitrogen gas from the emergency tanks to the cable oil system. The nitrogen is required to be extra dry and the cylinders are required to be dried out before the nitrogen is introduced. Since it is necessary to avoid contact of the oil in the emergency tanks with air at all times during normal operation these tanks are serviced by small auxiliary reservoirs of the expansible cell type which maintain positive oil pressure in the main tanks at all times. This oil piping system is shown in Fig. 7.

### Oil Pressure and Flow Characteristics

During installation great care was taken to maintain positive oil pressure at all times as a safeguard against accidental leakage and also during periods when cable ends were opened for terminal assembly. Under these conditions a predetermined value of oil flow must be maintained, just sufficient to prevent entrance of moisture or air. During operation the same problem exists and, in the case of submarine cable, the surrounding water pressure at different points of the profile must be considered.

Submarine cable in long lengths presents a more difficult oil feed problem than ordinary underground cable. The limiting conditions are, maintenance of positive oil pressure at middle of cable length during coldest winter weather, without exceeding a safe oil pressure on sheath at low water level under full load summer conditions. The armor gives some support to the sheath and the practise is never to exceed a pressure of 20 lb per sq in. at low water level. Water is more dense than oil. There is, approximately, 1 lb gain in head pressure of water for every 30 ft of depth, as compared with oil. The head pressure of oil is approximately $2^1/_2$ ft per lb.

The Columbia River crossing was particularly difficult because of the great difference (33 ft) between low and high water levels. The maximum depth in the middle of the channel at low water level is 30 ft, giving a depth of 66 ft at high water. After a careful study of conditions it was decided to use gravity feed reservoirs mounted at the same level (44 ft above low water) at both ends and feeding toward middle of cable length. This represented an oil pressure of 18 lb per sq in. on the sheath at low water level and left only 1 or 2 lb margin of oil pressure over water pressure at middle of length when load is dropped in the winter at high water level. The margin is sufficient, however, since the assumed conditions are extreme and of only transient nature, the pressure drop in the cable core lasting for less than an hour after load is dropped.

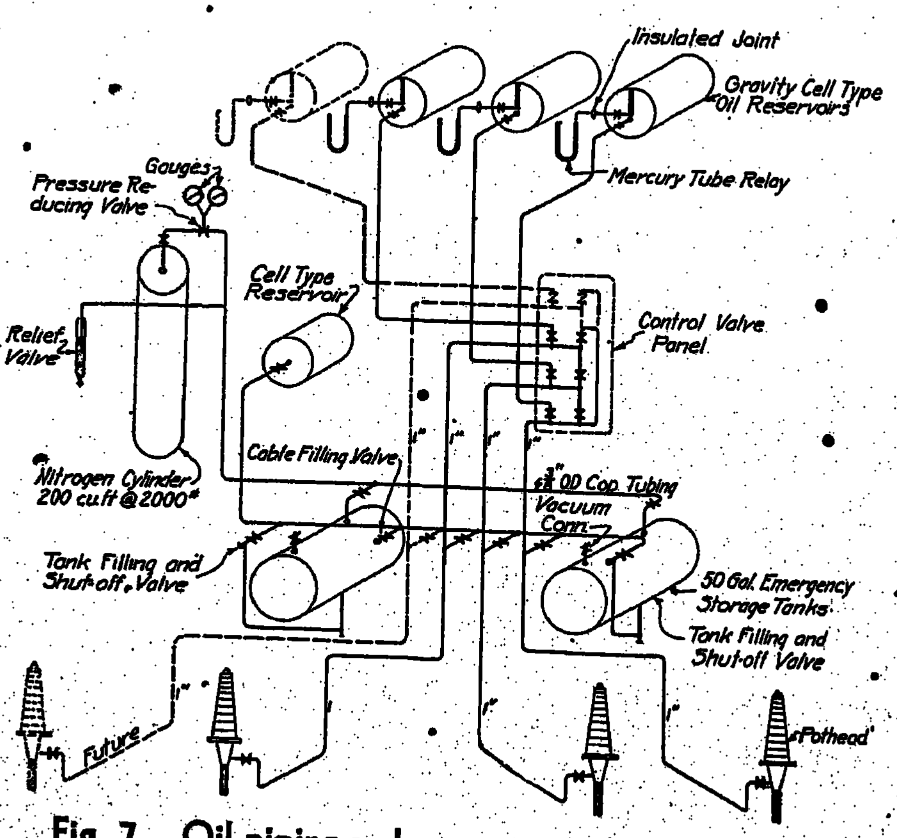

Fig. 7. Oil piping and arrangement for emergency oil supply

These limiting conditions, and the need of utilizing all available oil pressure, did not allow the use of restrictors for limiting oil flow in hot weather in case of accident. In the winter such restriction is not needed but in the summer the reservoirs would empty at a fairly rapid rate in case of a "full open" accidental leak in the system.

This question was given careful study. Space does not allow inclusion of details. Briefly summarized, the conclusions are:

1. The regular switch signal or the oil level alarm relays will give warning immediately or soon after the accident, allowing an emergency crew to be on the scene within 1 or 2 hr.
2. The position of the failure, and other factors, will determine whether the reservoirs involved are exhausted of oil by that time. If not, the emergency oil supply is turned on and the nitrogen gas pressure adjusted (20 lb limit) to maintain an oil flow not greater than 6 gal per hr. This will entirely prevent entrance of water or air in the system and the flow can be maintained until the damage is located and repaired.
3. Even if one or more reservoirs are found exhausted the water will enter the cable core very slowly, if at all, and will have traveled only a short distance by the time the crew arrives. Emergency oil flow will then be adjusted as described, the oil leak located and the cable picked up, not at point of leakage, but 200 ft on each side. It will be cut under oil flow at these points and tested for moisture, repeating the operation in 100 ft steps if necessary. A length of replacement cable will then be spliced in.

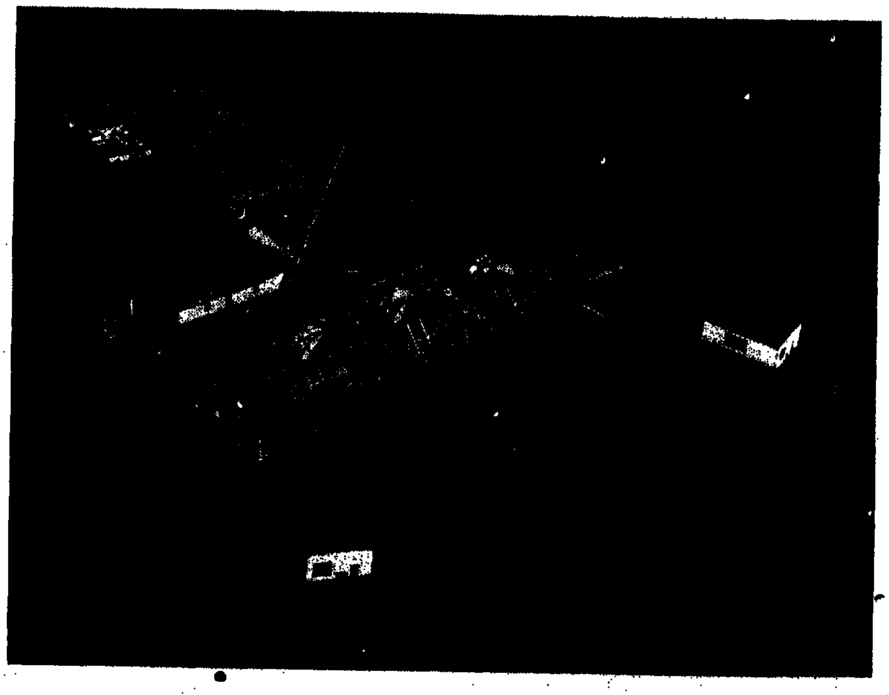

Fig. 8. Floating equipment used while laying cable

The repair joints, held in stock for such emergency use are of standard design successfully used in previous conduit installations with the exception that the spun copper casing is protected by a cylindrical armor box having bolted armor clamps at each end. The cable paper is stepped and the usual low loss varnished cambric tape used for reinforcement wrappings. The halved connector is of the double shut-off plug design that has proved so successful in the past. The copper casing is 3 ft 8 in. long by 6 in. diam. The armor box is 4 ft $2^1/_2$ in. long by 8 in. diam.

## Installation Procedure for the Columbia River Cable

THE importance of the 115-kv submarine cable crossing of the Columbia River, the unusually great size of the reels of cable, and the fact that this was the first submarine installation of oil filled cable to be made in this country, set a task of a new order for the construction forces, and created many unusual construction problems.

Several weeks before the installation was started, a school was set up for the construction personnel and intensive training was carried out. This included such work as making up pothead connections by the use of short lengths of scrap cable. Undoubtedly it was this training together with very careful engineering of the construction work that enabled the installation to be made without serious mishap.

### BARGE EQUIPMENT

Equipment suitable for laying the long heavy lengths of submarine cable was difficult to assemble from a harbor the size of Portland's, and it was only after considerable effort that necessary equipment at a reasonable rental cost was obtained. This equipment as finally assembled consisted of a flat-deck barge, 400 ton capacity, 125 ft long, 32 ft wide, on which the 3 cable reels for each crossing and control equipment were placed. As auxiliary to the cable barge, a steam dipper dredge barge was utilized as a derrick, and in addition there were 2 small gasoline donkey scows from the Port of Portland's dredging equipment, a spare flat-deck barge for use as spare deck space, and 2 small derrick tugs, one for use in changing anchor lines and anchors and one for emergency.

The main barge was arranged for laying the 3 cables at each crossing simultaneously, the reels being mounted in tandem for proper deck load distribution. The 2 reels nearest the laying end, or stern of the barge, were raised sufficiently to allow the cable from the reel forward to pass underneath. Easy running rollers were placed at such points as to eliminate all possible friction. An overhanging timber structure was constructed at the stern of the main barge, with rollers arranged for a minimum safe bending radius of cable as it was fed overboard, and which spaced the cables 4 ft apart. The 2 flanges of each reel were equipped with friction band brakes, one used for laying control and one for emergency.

Calculations for running lines and strains when laying the cable were made on the basis of maintaining the main barge sidewise to river current, which at the time of laying was approximately 7 miles per hr. A donkey scow was placed at bow and stern on the upstream side of the cable barge. Two steel lines, with large anchors attached from each of the donkey scows, were maintained upstream while laying and moved in successive steps across the river. The derrick barge was held alongside the main barge on the downstream side, with steel lines, also with anchors attached, extending from the donkey drums at bow and stern for control of movement across the river. These anchors were also moved as required. The derrick tugs mentioned were used for changing anchors and to clear lines of driftwood, trees, etc., which were quite heavy at this flood stage of the river. The general arrangement of the equipment is shown in Figs. 8 and 9.

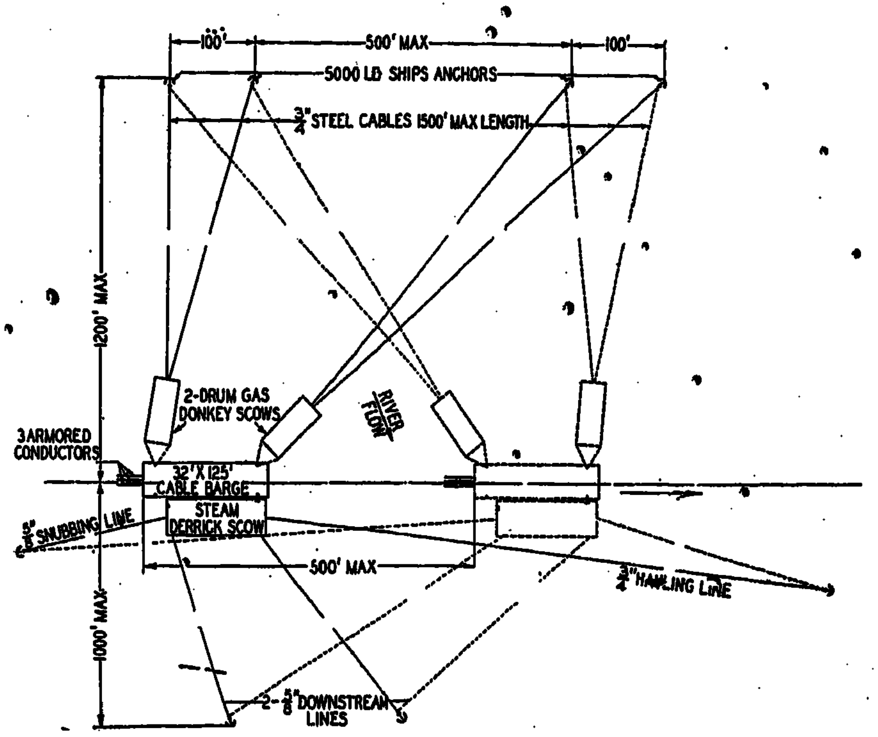

Fig. 9. Arrangement of floating equipment used for laying cable

Buzzer and bell signals were provided to each operation control point. One control was from the point where the cable went overboard, controlling slack and reel movement; another point controlled barge movement across river and the upstream anchor lines from the donkey scows. This control point was in turn controlled by telephone from the shore where men with transits were located for alinement of the cable.

### LAYING THE CABLE

The shorter sections of cable across the Oregon Slough (see Figs. 1 and 2) were laid first, and on a rapidly rising river. The 3 shore ends, one at a time, were pulled over rollers located at frequent intervals, into terminal structure No. 4, by means of lines from derrick hoisting drums fastened to the armor pulling eyes at the cable ends. (The terminal structures are numbered consecutively from 1 to 4, beginning with the one farthest north, as indicated in Fig. 2.) Cables were then clamped in final position with necessary slack above terminal pedestals for terminal installation.

Temporary oil connections were made between the 3 cable ends and the 3 permanent oil pipings which had been installed with permanent oil reservoirs, emergency oil tanks, etc., previous to cable laying operations. Oil supply to the cable was then made from the permanent oil supply apparatus, oil supply to the cable from the temporary pressure reservoirs shipped with the reels being closed off. Reserve supply of oil and the degasifying equipment were connected and made ready to provide against any possible emergency that might arise. After all connections were complete, short slacks were laid just outside terminal No. 4 and temporarily anchored, and the laying of the Oregon Slough crossing started. This laying to a point approximately 300 ft from terminal No. 3, where slack was to be dropped, took 5 hr. Slack, as engineered for this location, was laid out on the deck of the spare barge and lashed in place to cross timbers which were later raised with the derrick and the spare scow pulled from under the suspended cables. The suspended cables were then carefully lowered to the bottom of the river, later checked by a diver as to lay, and then the lashing cut allowing timbers to float to the surface of the river. The laying equipment was then moved to terminal No. 3, the shore end footage of the cable pulled from the reels and placed in the shape of a figure 8 on the deck of the spare barge. Reels were then removed from the main barge deck, ends of the 3 cables were pulled into terminal No. 3 and clamped into proper place. The 3 cables were then one at a time moved over toward the edge of the barge and carefully lowered overboard in final location alongside.

Laying of the 3 longer sections across the main channel was more difficult on account of the extreme high water and heavy current, but was accomplished in the same manner as the Oregon Slough crossing. Laying of these lengths was started from structure No. 1 on the Washington side of the river and laid to terminal No. 2. The crossing time of the river proper was approximately 14 hr, the following 2 days being used in disposing of slack at the outer edge of the 800 ft sand bar and working the barge equipment through the dredged channel to structure No. 2.

The same preparations were made at No. 1, where cable ends were first temporarily connected to the permanent oil reservoir system for any oil emergency condition, as were made at No. 4. These preparations were called into use shortly after the laying process started.

When about 1,000 ft from structure No. 1, the oil pipe connections between the inner end of the cable and the oil reservoirs contained within the reel body was sheared off on account of creepage movement of the inner layers of cable. The man handling the emergency oil apparatus at structure No. 1 immediately noticed a drop in oil pressure and, as instructed, supplied the emergency oil, maintaining the established pressure. Before the crossing of the main channel was completed the oil connections on the 2 remaining cables were also sheared off, also owing to the slippage of the inner layers of cable on the reel drum. The leaks thus developed could not be closed until sufficient cable was taken from the reels to allow access to the inner layer, and at one time it was problematical as to whether there was a sufficient supply of degasified oil available to maintain oil pressure on the cable until oil leakage from broken connections was stopped.

### Terminal Installation

After the cable laying was completed, terminal pothead installation was immediately started at terminal No. 3, the necessary oil flow from cut cable ends being supplied from the permanent oil system through the temporary oil piping at terminal structure No. 4. No difficulty was experienced at any time during installation. The entire structure was temporarily covered with canvas to protect the working deck from rain and, in turn, each terminal location was inclosed with a special tent during taping and terminal assembling operations.

Terminals were next installed at terminal structure No. 4 with oil control for operations at this point through the cable from the permanent oil system at No. 3. The same procedure in rotation was followed for the terminal installation at structures Nos. 2 and 1. In all terminal assembly operations, as well as at other times, telephone communication was maintained between all 4 structures. This communication between structures allowed very close regulation of required oil flow and pressure during terminal installation and also for the final adjustment and testing of the entire oil system.

Aside from the broken oil connection, no difficulty of any serious nature was experienced during the entire installation of cable and terminals.

### Tests and Operation

As soon as the installation was completed a 3-phase 60-cycle short-circuit current heat run was made, temperatures, induced sheath and armor currents, oil volume changes, etc., being carefully measured. This heat run served a 2-fold purpose: it caused

**Table I—Comparison of Calculated and Heat Run Data**

| Circulating Current* (Avg) | | 840 Amp Load | 795 Amp Load |
|---|---|---|---|

uniform dispersion and absorption of any small amounts of impurities that might not have been excluded, and it furnished a final check on all theoretical calculations. Table I gives a summary of these calculations and the essential heat run data.

Operation of the cable under normal conditions since June 19, 1932, to date has been very satisfactory. Cable temperatures and oil level fluctuations have followed the calculated values very closely with varying load conditions.

# Further Research in Injuries From Electric Shock

By
W. B. KOUWENHOVEN
MEMBER A.I.E.E.

O. R. LANGWORTHY

Both of The Johns Hopkins University, Baltimore, Md.

**With approximately 2,500 persons suffering from electric shock annually in the United States, fatally in about 50 per cent of the cases, the problem presented is one of increasing importance. In recognition of this fact, intensive experimental work has been under way at The Johns Hopkins University for some time, supported by funds made available through the generosity of the Committee on Physiology of the Conference on Electric Shock. The accompanying article discusses the effects of injuries produced by surge discharges, and summarizes some of the more important conclusions previously published in ELECTRICAL ENGINEERING.**

ACCIDENTS caused by electric shock in general and by contacts with low voltage circuits in particular are increasing in number with the increasing industrial and domestic use of electrical equipment. Case analyses have shown that individuals between 15 and 30 years of age are most likely to be the victims, perhaps owing to the greater carelessness of youth; and that more men are injured than women. Also, accidents have been found to be more common during the summer months as a result of reduced protection by clothing, and the presence of perspiration which decreases the skin resistance. To supplement the analytical study of the case history of several hundred unfortunate human victims of electrical accidents, laboratory experimental work has been carried on for some time by The Johns Hopkins University in an effort to learn enough about the physiology involved to enable the determination of effective remedial measures that will save human life.

In this laboratory work the injuries produced by electric currents have been studied through analyses of the effects of shocks upon living animals completely anesthetized. Animals differ widely in their ability to withstand electric shocks; dogs are killed by a relatively small current, while rats are much more resistant. The difference lies to a great extent in the behavior of the heart; the adult dog's heart readily is thrown into ventricular fibrillation by a small electric current, and does not recover from that condition spontaneously, whereas the ventricles of a rat's heart apparently do not fibrillate. By ventricular fibrillation is meant the failure of the ventricles of the heart to beat with a coordinated rhythm, the individual muscle fibers contract asynchronously instead.

While these wide variations in reaction make difficult the direct application to man of the results obtained experimentally from animals, the variabilities noted prove to be an aid rather than a hindrance to the progress of experimental work provided the proper animal is selected and the different reactions are kept well in mind. Thus, the authors have used the rat in their studies of the changes in the nervous system, and the dog in their studies of ventricular fibrillation; all animals of course thoroughly anesthetized throughout the entire experimental procedure. The essential features of this experimental work have been covered in previous issues of ELECTRICAL ENGINEERING:

1. "What Are Effects of Electric Shock?" June 1931, p. 406–10.
2. "Nerve Injuries From Electric Shock," December 1931, p. 929–32.
3. "Heart Injury From Electric Shock," April 1931, p. 242–4.

The present article includes results from some new work with an impulse generator, and summarizes a further analysis of previous work.

## INJURIES FROM SURGE DISCHARGES

As the surge or impulse generator is used more and more widely in industry, there has arisen the question

---

Written especially for ELECTRICAL ENGINEERING. *Not published in pamphlet form.*

of the danger to life of shocks received from it. In an attempt to obtain some indication of the correct answer to this question, several experiments have been conducted with a small impulse generator, the only resistance in the circuit being the body of the animal under test. Cathode oscillograms showed that under these conditions the current reached a value slightly in excess of 100 amp at 200,000 volts maximum. The steepness of the wave front is shown by the fact that the current reached its maximum value in $^1/_4$ microsecond, with the entire discharge completed in about $4^1/_4$ microseconds. With this apparatus several rats were tested with the results shown in Table I.

With group 1, a clip attached to the desired part of the body and extending several inches above the animal attracted the spark to a particular location. All of the 7 rats tested breathed spontaneously and were active immediately following the shock. The only evidence of abnormality was in the 2 that had received the discharge at the level of the shoulders; their sense of equilibrium was disturbed, and they rolled around in small circles for some 10 minutes, after which they were quite normal. It is evident that under these conditions little or no damage was produced by the surge discharge.

In the second group where 5 rats were suspended so that the surge traversed the entire length of the body, all died despite the use of artificial respiration. In only one of these rats was heartbeat noted following the shock; this rat made a few attempts to breathe, but died ultimately in spite of long continued efforts with artificial respiration. In this group of animals, rhythmic tremors of the striated musculature were observed most markedly in the hind legs.

Table I—Results of Surge Shocks on Rats

| Group | Path of Surge | No. | Recovery | Breathing | Heart Beat | Resuscitation |
|---|---|---|---|---|---|---|
| 1 | Surge entered at: | | | | | |
| | Head | 3 | 3 | Normal | Normal | None needed |
| | Shoulders | 3 | 3 | Normal | Normal | None needed |
| | Rump | 1 | 1 | Normal | Normal | None needed |
| 2 | Tail to head | 4 | 0 | None | None detected | Failed |
| | Back of head to tail | 1 | 0 | Feeble | Feeble | Failed |
| 3 | Back of neck to tail | 4 | 0 | Feeble in 1; none in others | Feeble | Failed |
| 4 | Shoulders to tail | 4 | 3 | 1 normal; others feeble | Normal | Not needed on 1; successful on 2 |
| 5 | Middle of back to tail | 4 | 3 | Normal | Normal | Failed on the 1 requiring it |
| | Right fore leg to tail | 3 | 2 | 1 normal; others feeble | | Not needed on 1; 1 successful; 1 failure |
| | Left fore leg to tail | 4 | 1 | 1 normal; others feeble to none | | Not needed on 1; others failure |
| 6 | Back of neck to abdomen | 4 | 1 | Feeble to none | Feeble | Successful on 1 |

In Group 1 experiments the rats lay on the ground plate. All other experiments were made with the rats suspended

The brain itself was not included in the path of the discharge applied to group 3, but the brain stem and the areas controlling the heart and respiration lay close to the electrode. In all 4 cases the injury to the heart proved fatal in spite of artificial respiration, and in spite of the fact that the heart damage was not so great as that noted where the discharge traversed the entire length of the body.

The 4 animals of group 4 were tested with the surge entering at the level of the shoulder and passing from the tail to the ground plate. Under these conditions, the portion of the brain that controls the heart and lungs did not lie in the direct path of the discharge. One animal breathed at once following the injury and recovered quickly. Another started to breathe spontaneously, but stopped and was saved by artificial respiration. The third also was resuscitated successfully, but the fourth died in spite of initial attempts to breathe. In all these animals their hearts beat strongly following the surge discharge. Marked tremors also were noted, and in one animal the hind legs were weak for an hour after the shock, subsequently becoming quite normal.

Following a surge discharge passing through the 4 animals of group 5 from the mid-thoracic region to the tail, all breathed spontaneously and the heart of each beat strongly following the shock. In one case, however, the breathing subsequently ceased and the animal could not be resuscitated. Also, several animals were tested by being suspended from one fore leg, the spark passing from the tail to the ground plate with the results as noted in the table.

In the tests on group 6 the discharge entered at the back of the neck and left in the mid-abdominal region. On the 4 animals tested in this manner, artificial respiration was used in every case, but with only one recovery. In all animals the heartbeat was weak following the discharge, but improved considerably during the next few minutes. Clonic movements followed the passage of the discharge.

As evidenced by earlier experimental work the heart of a rat is usually but little influenced by electric shock. This, however, is not true in the case of lightning discharge, under which condition the action of the rat's heart was in many cases definitely affected. Immediately following the discharge, either no heartbeat could be detected, or the heart was very feeble, but there was no evidence of ventricular fibrillation. Although in almost every case the discharge of the lightning generator used in these tests produced tremors in the musculature, there was but little evidence of the severe muscular contractions noticed in the earlier experiments with d-c and a-c circuits; in these impulse experiments the chests of the animals were expanded following the discharge.

These experiments with the surge generator again clearly emphasize the importance of the current path through the animal, and check the results already reported for the various current pathways. It is evident also that the amount of nerve tissue lying in the current path bears a direct relationship to the damage to the organism. In the tests, as the brain and nerve centers were eliminated from the current path, the chances of recovery became greater.

## SUMMARY OF EFFECTS PRODUCED BY ELECTRIC SHOCK

Some of the factors of greater importance in cases of electric shock will be summarized in the following paragraphs.

The effects of voltage as indicated by the experiment with rats showed clearly that low voltage a-c shocks are more deadly than d-c shocks of corresponding voltage; that d-c shocks on a 1,000-volt circuit were more deadly than a-c shocks of corresponding voltage; that in either case the injury increases with the increase in voltage.

### Table II—Effects of Voltage

| Voltage | Number Tested | Duration of Shock Sec | Current Milliamp | Per Cent Receiving Artificial Respiration | Per Cent Paralyzed | Per Cent Died | Per Cent Immediate Recovery | Average Resistance Ohms |
|---|---|---|---|---|---|---|---|---|
| A-C—110 | 11 | 10–30 | 25–48 | 90 | 9 | 27 | 64 | 3,091 |
| D-C—110 | 33 | 5–60 | 28–47 | 30 | 3 | 12 | 85 | 2,685 |
| A-C—220 | 28 | 5–14 | 80–200 | 93 | 38 | 34 | 28 | 1,890 |
| D-C—220 | 19 | 5–30 | 100–200 | 74 | 5 | 42 | 53 | 1,635 |
| A-C—500 | 26 | 1–4 | 240–490 | 73 | 50 | 12 | 38 | 1,425 |
| D-C—500 | 37 | 1–4 | 280–640 | 89 | 5 | 46 | 49 | 1,385 |
| A-C—1,000 | 28 | 1–4 | 650–1,200 | 85 | 39 | 32 | 29 | 1,140 |
| D-C—1,000 | 31 | $^{1}/_{10}$–1 | 600–1,100 | 97 | 13 | 58 | 29 | 1,365 |

The danger of contact with high voltage circuits is recognized widely, but the serious and far more prevalent hazard from contacts with low voltage a-c circuits in residences and factories as yet is not sufficiently widely understood for public safety. The danger of contact with low voltage circuits increases as the contact resistances of the body are lowered. When a person who is well grounded comes into contact with a low voltage circuit through a defective electrical device or otherwise, the value of the current may be sufficient to cause death. The majority of such accidents occur in bathrooms, damp cellars, around water and gas piping, and other places where local conditions reduce to a negligible value the contact resistance of the body.

When contact is made with a high voltage circuit, the contraction of the muscles is so violent that often the victim is thrown clear, whereas it is difficult if not impossible for the victim to release his hold in cases of low voltage shock because the muscular contraction is steady rather than violent. When the body forms part of an electric circuit it offers 2 resistances to the passage of current: the contact resistance, and the ohmic resistance of the body proper, that in the case of human beings amounts to approximately 200 ohms. The contact resistance offered by the calloused palm of a laborer may be 100,000 ohms per sq cm, whereas with moisture present that same resistance may fall to 1,200 ohms or less per sq cm. Analyses of experimental data show that the contact resistance drop is of the form of a voltage drop which is practically independent of the current flowing.

In human beings electric currents of from 8 to 10ma are quite painful; at 20ma the muscular contraction is so great that the victim cannot release his hold on the circuit; a current of from 90 to 100ma is considered dangerous.

In human accidents only the voltage of the circuit usually can be determined, leaving in doubt the value of current flow through the body. Sensitivity to electric current varies widely in different individuals and various animals; in general the threshold of sensitivity ranges between 0.5 and 2ma. Experiments reported upon by other qualified investigators have demonstrated that in dogs a current of from 70 to 80ma flowing through the body produces ventricular fibrillation of the heart; that larger currents may cause sufficient muscular contraction to inhibit all heart action. In these latter cases the heart usually resumes rhythmic beat when the circuit is opened.

Not only is total current through the body of importance, but the current density also must be considered. In their laboratory experiments, the authors found that a small animal could not recover from a given shock so readily as could a much larger animal. Perhaps this is one of the reasons for the belief that thin people are more susceptible to electric shocks than are large individuals.

The duration of the contact with electric circuits is of extreme importance in determining whether or not the victim will survive. In general, the hope of successful resuscitation dwindles as the time of contact and the voltage of the shock is increased.

Usually in cases of human accidents but few data are available to reveal the length of time the current flowed through the body of the victim. Fortunately, because of the violent muscular contraction when contact is made with high voltage circuits, the shock is usually of short duration. In cases of low voltage shock, however, the person may be held in contact with a circuit for an appreciable time. Laboratory experiments with animals have borne out the vital importance of the time factor.

Human beings sometimes retain full consciousness while in contact with an electric circuit and are able to call for help, whereas others are rendered unconscious at once.

If the victim recovers, consciousness may return after a few seconds or minutes, and usually the victim is able to return immediately to his work provided the injuries inflicted by the current are not severe. In some instances, however, the unconscious state passes into a deep coma which in turn is interrupted by violent convulsions terminating in death. There are on record several accidents in which unconsciousness followed a shock between 2 fingers of the same hand, or 2 points on the same leg. In such accidents no current flowed through the central nervous system, and the resulting unconsciousness must have been due to the sudden shock and the resulting vasomotor reactions.

That shocks may cause a "block" in the nervous system that will inhibit respiration has been demonstrated conclusively. If artificial respiration is applied promptly and continued for a sufficient time the respiratory nerve center may have opportunity for successful recovery.

Extensive laboratory experiments substantiate the value of prompt and long sustained artificial respiration. In the microscopic examination of the nerve tissues of test animals the injury to the nerve structure was demonstrated clearly. In those animals which could not be induced to breathe following the shock the cell damage was most marked; in some instances the severity of the nerve cell injury was incompatible with life.

Hemorrhages have been found in the spinal cords of many of the rats subjected to laboratory shocks, but injuries of this type are not found in the case of human accidents.

In several animals, however, hemorrhages were found both in the substance of the medulla oblongata and filling the fourth ventricle of the brain; similar hemorrhages are common in legal human electrocutions. Apparent hemorrhages in the lungs have been noted in the case of some human accidents, a condition noted also in the laboratory experiments. Excepting only those which distended the fourth ventricle pressing on the respiratory center and those occurring in the spinal cord, the hemorrhages found in the brains of the rats seldom were responsible for the death of the animals involved.

Convulsions are recorded occasionally as following an electric shock in human accidents, a phenomenon observed also in several of the experimental animals.

The animals so affected were found to be hypersensitive to all sensory stimuli after the shock. In a few cases there was evidence of disturbance to the vestibular mechanism, as shown by the animals walking or running in circles.

The human heart seldom recovers spontaneously from the state of ventricular fibrillation. Some observers of electrical accidents believe that the majority of deaths are caused by this abnormality. Therefore the action of electric current upon the heart is of the greatest importance.

As yet, no specific method has been developed for the recovery of the fibrillating heart in human beings. Nevertheless, in accredited experimental work carried on by other investigators, it has been demonstrated that the fibrillation in a dog's heart can be stopped by the injection of a potassium chloride solution into the carotid arteries. The injection of this solution inhibits all contraction of the heart musculature. The solution is then washed out with physiological saline solution and the heart resumes its normal rhythm.

Permanent disability following electric shock is shown by only a very small percentage of the individuals who have recovered from an electric injury.

Extensive burns following actual contact may be slow in healing, and nerve ends sometimes get caught in the scar tissues thus producing a lasting irritation. In a few instances cataracts of the eyes have been found, and in others, instability of the nervous system for an appreciable time following the shock has been noted. How much of this is caused by actual damage to the nerve cells, and how much should be classed as neurosis, is difficult to say. According to reports published in Germany in 1931, there seems to be the possibility that muscular atrophy may follow electrical accidents either soon or after several months' delay. It is reported that this effect usually is preceded by pain and abnormal sensations in the extremity, and accompanied by vascular disturbances. These data are interesting, but they must be examined critically. In the literature of England and the United States no similar cases of atrophies following electric shock have been found. It is of particular importance, therefore, that these late effects be watched for carefully in the future.

## CAUSES OF DEATH

It is recognized that the heart and the respiratory center in the brain are particularly susceptible to injury by electric currents. From the authors' experimental work with animals and from their analyses of reports of human accidents it is evident that death as an ultimate result of electric shock may occur from several different direct causes:

By asphyxiation caused by the prolonged muscular contraction.

By ventricular fibrillation of the heart, usually believed to be inducted by low voltage shocks.

By destruction of nerve cells in the respiratory center of the brain.

By excessive increase in body temperature as a result of the Joule effect of the shock current.

By severe burns or other resulting complications.

Competent authorities stress the fact that in electrical accidents death often is *only apparent.* Artificial respiration should be begun *immediately* following an accident and continued until the patient recovers or until the cessation of life as an actuality is evident by the onset of *rigor mortis.* Accredited reports list many successful resuscitations following the application of the Schaefer prone pressure method of artificial respiration, in one case success following an 8-hr. effort.

# Conductor Vibration on Transmission Lines—III

**Field tests made in California on a double circuit tower line comprising one aluminum and one copper circuit show that these different types of conductors vibrate under approximately the same conditions and at about the same frequencies, aluminum vibrating with the greater amplitude.**

By
J. A. KOONTZ, JR.
MEMBER A.I.E.E.

Pac. Gas & Elec. Co.,
San Francisco, Calif.

A CAREFUL STUDY of the vibration problem on the lines of the Pacific Gas and Electric Company (Calif.) was undertaken after trouble had developed in some of the early damper designs of the Stockbridge type. This trouble was due to fatigue of the supporting messenger strand. Life tests made on these early assemblies soon revealed the necessity of substituting high strength steel strand in place of the ordinary guy strand or Siemens-Martin grade. This substitution changed the characteristics of the damper slightly, but later tests proved that the dampers still were effective. The life tests were made on the damper assemblies using a vibration machine similar to that shown in the Monroe-Templin paper (Fig. 7, p. 487, ELEC. ENGG., July 1932). The revised damper design using the high strength steel was given a life test of more than 100,000,000 cycles without failure. The failures in the supporting strand occurred not at the center clamp or point of maximum stress, but where the cable enters the weight; a point where the strand is subjected to a reversal of stress.

Mr. Monroe and Mr. Templin seem to favor 2 dampers per wire per span wherever possible. I prefer using 4 dampers for any line conductor of 1-in. diam or larger. These 4 dampers should have their spacing so staggered that not more than one damper would be located at a node point for any of the frequencies most often experienced. This method as a rule permits 3 dampers to be so located that they may be fairly effective as dampers. A damper has its greatest efficiency when located at the center of a loop, and the Stockbridge damper is most efficient when the natural period of the damper is approximately that of the vibrating cable. To make a more careful study of damper spacing a test span was

---

Full text of a discussion submitted concerning the Monroe and Templin paper "Vibration of Overhead Transmission Lines" published in the July and August issues of ELECTRICAL ENGINEERING and previously presented at the A.I.E.E. summer convention, Cleveland, Ohio, June 20–24, 1932. *Not published in pamphlet form.*

erected and this span was vibrated mechanically at from 4 to 22 cycles per second. After studying the damper spacing on this short span the test equipment was transferred to the field, and spans actually in service on line towers were vibrated to obtain data against which the laboratory results might be checked. These tests all seemed to indicate that the use of 4 dampers with staggered spacing was much more satisfactory than the use of only 2 dampers. With modern dampers of the Stockbridge type properly designed and located, I believe vibration can be controlled so effectively that no damage will be done to the conductor.

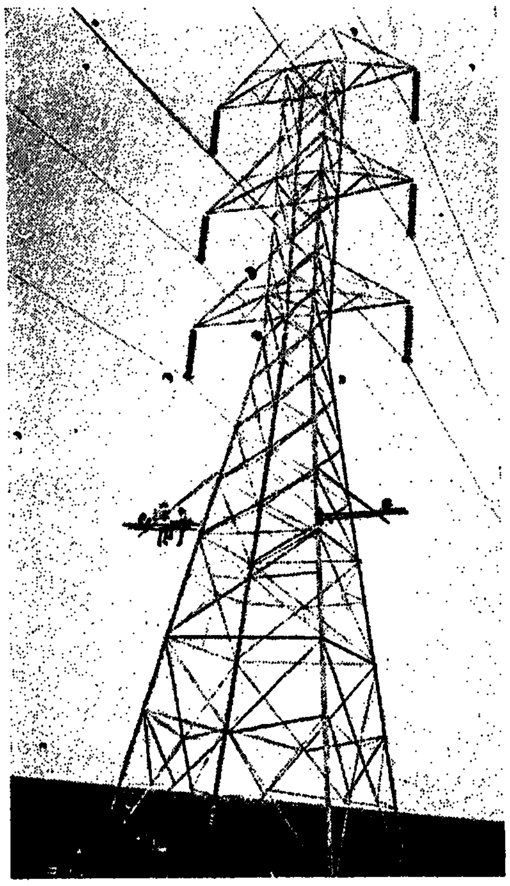

**Fig. 1. Mounting of recorders on a tower line having one aluminum and one copper circuit**

Records were taken while the lines were in operation (the aluminum line at 165 kv and the copper line at 220 kv) by placing the instruments on platforms 20 ft beneath the lower conductors to which the recorder actuators were connected at points about 6 ft from the suspension clamps by means of special cords. Conductors: A.C.S.R., 795,000 cir mil, 1.093-in. diam; copper, 509,400 cir mil, 4CS hollow core, 1-in. diam

Most of the testing was done on an aluminum line consisting of 3 795,000-cir-mil steel core aluminum cables having a conductivity equal to 500,000-cir-mil copper, and strung as one circuit on a double circuit 220-kv tower line. On the opposite sides of the same towers there are 3 hollow core copper cables of 1-in. diam having a section of 509,400 cir mil. The 2 sets of cables are parallel, with only 27-ft horizontal separation; they have the same ground clearance and hence have the same sag, and are supported in the same manner. Therefore, all spans are alike. This line represents almost ideal conditions for the checking of relative vibration on these 2 types of conductors.

A study of the relative vibration of the 2 types of conductor was undertaken and vibration recording equipment to take simultaneous records was installed and arranged as shown in Fig. 1. Observations were made for several weeks at a time when conditions were rather favorable for vibration. The data from the field tests are shown clearly in Fig. 2, where it may be observed that the copper and aluminum cables vibrated at approximately the same time. Loop lengths were observed to be of the same magnitude and the conductors vibrated at approximately the same frequency, but the amplitude of vibration of the copper conductors was less, as may be noted.

There is one other point to which attention should be called in connection with the vibration of transmission line conductors. Vibration in general occurs during the night hours, late in the evening, or quite early in the morning; the wires seldom vibrate during the usual working hours of the day. This point has led some engineers to believe their lines free from vibration.

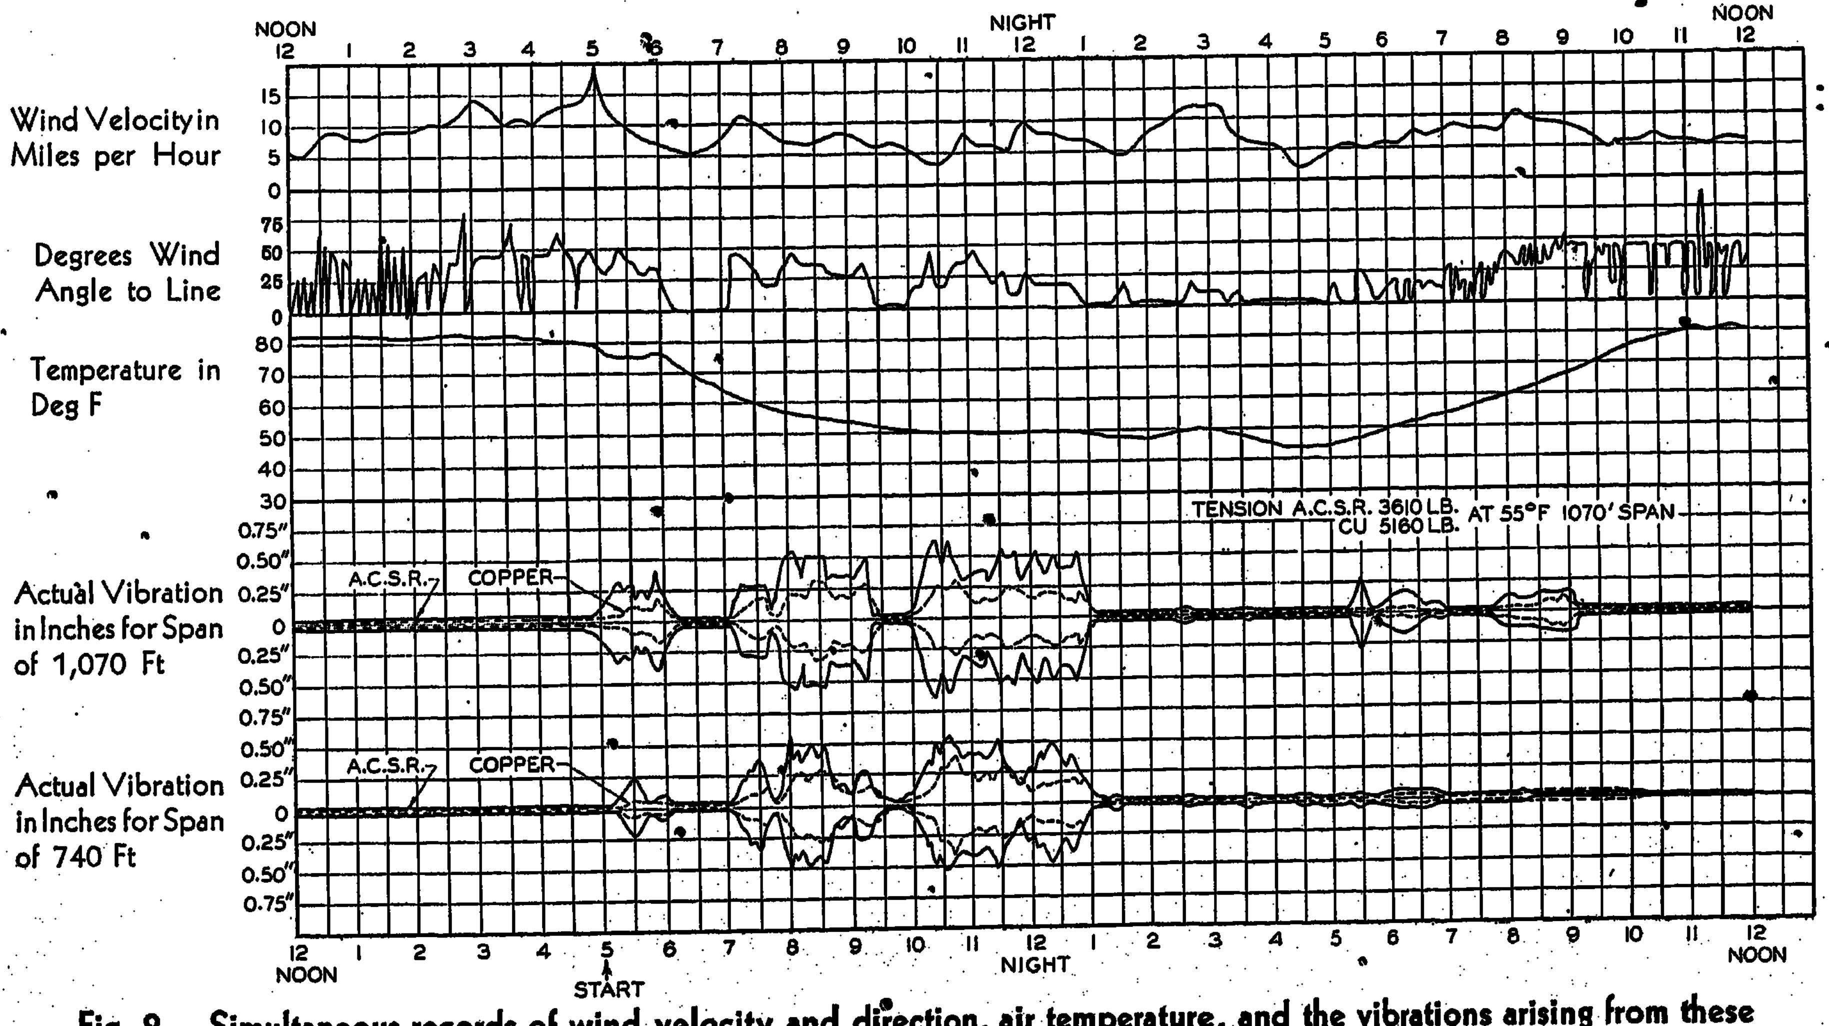

**Fig. 2. Simultaneous records of wind velocity and direction, air temperature, and the vibrations arising from these conditions in parallel copper and aluminum conductors. Smoked chart records were taken through a 24-hr period beginning at 5 p.m., May 8, 1932**

# Adult Technical Education in Metropolitan Areas

By
O. W. ESHBACH
MEMBER A.I.E.E.

Am. Tel. & Tel. Co.
New York, N. Y.

**A plea for careful study of the advantages to be gained through properly coordinated efforts in, and facilities for, intermediate technical education and postgraduate work.**

PROFESSIONAL progress of our engineering societies has been and always will be influenced by the education of their members. Whether that education is recognized by professional degrees or is secured through pursuit of non-academic technical instruction is unimportant. It is, however, of interest and importance to know about the agencies contributing to the training of the potential professional engineering group, and how they may be made more effective in meeting the demands of this group.

In recent years through the investigation made by the Society for the Promotion of Engineering Education, attention has been directed to the entire system of engineering education. During the past year the educational committee of the Institute has given consideration to many of the problems brought forth by these and other studies. Affecting all of these problems is a general educational movement that for some time has been gaining in importance, but which only recently received organized recognition in the form of "adult education." It is the purpose of this paper to point out some of the possibilities in the development of adult education as they affect technical education and the providing of technical employees for industry.

## Supply of Engineering Graduates

In recent years, the employment of college graduates has been of no small concern. Figure 1 shows clearly what has taken place from the days of intense competition, 1924–29, up to the present time, when satisfactory employment is almost impossible. While this situation is of concern today, it is quite possible that the next 5 years will see a recurrence of the conditions that existed 5 years ago, for it is apparent that business conditions affect freshmen enrolments, with graduations reflecting these conditions 4 years later.

Whatever the situation may be, it is important to have some idea of the long term needs for engineering graduates as compared with the supply. An attempt in this direction was made by the National Industrial Conference Board a few years ago in a study of typical industries that seemed to show that 40,000 technically trained men could be absorbed by industry each year. This does not mean only professional engineering graduates, but includes all men with technical training. The recent study of technical institutes seems to show that from 40,000 to 50,000 men with intermediate training can be absorbed in normal times by industry, trade, and technical services. It is further stated that the ratio of engineering graduates to this group is approximately 1 to 3, which fact indicates that the present supply of engineering graduates should nearly meet the normal needs.

The normal demands for men with training perhaps equivalent to only half that of the 4-year undergraduate course do not seem to be met by schools established for that definite purpose, for the supply from this source is only approximately 1,500 a year. However, there are 15,000 non-graduates of engineering colleges each year who drop out of school and go to work in industry, not all of whom, by any means, lack adaptability to technical pursuits. Also, there are thousands of high school and vocational school graduates who, after entering industry directly from such schools, continue study in evening technical schools.

In 1930, out of 111 engineering colleges, 22 reported a total of 16,000 students enrolled in evening courses, of which number about half were studying for engineering degrees, while 1,760, or 11 per cent, were receiving credit toward advanced degrees. Among the evening school students are many of the group of non-college graduates who have dropped out of day school. Although records indicate that only a few of them ever will receive engineering

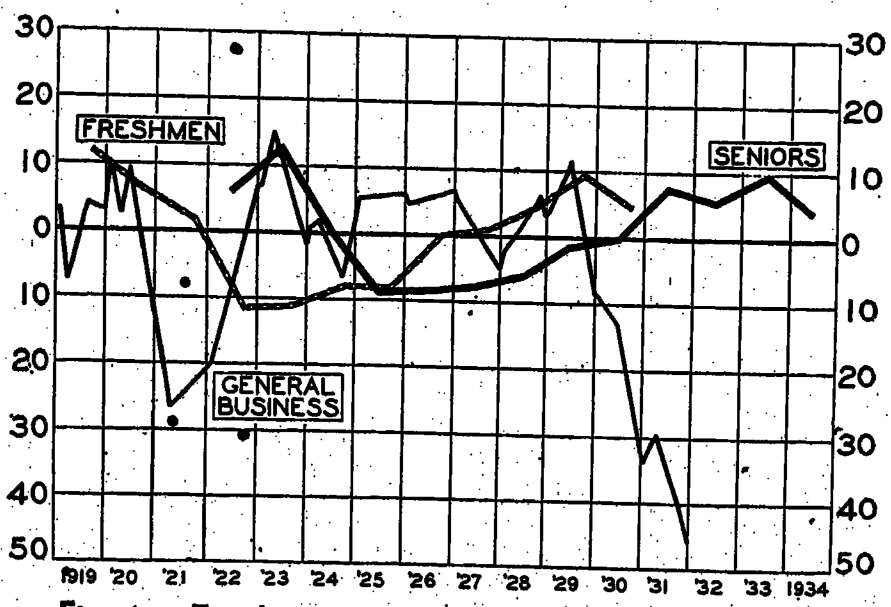

Fig. 1. Enrolment in engineering colleges and volume of general business as compared with "normal"

---

Based upon a paper presented informally at the A.I.E.E. summer convention, Cleveland, Ohio, June 20–24, 1932. *Not published in pamphlet form.*

degrees, a sufficient number of them are adaptable to technical careers and meet a substantial part of the requirements of industry.

### Importance of Evening Educational Facilities

It is a characteristic of our 145 undergraduate engineering schools that many of them are located in relatively small communities, and that upon graduation their students migrate to the larger metropolitan and industrial areas. It is in these areas that the greatest possibilities are offered for the development of postgraduate instruction as well as other forms of engineering education, such as coöperative courses and intermediate technical instruction.

In the 1930 Census the United States Department of Commerce called attention to 95 metropolitan districts which it had established upon the basis of each having an aggregate population of 100,000 or more, and containing one or more central cities of 50,000 or more inhabitants. (Fig. 2.) In these districts is approximately 44 per cent of the total population of the United States. It is safe to say that more than $^3/_4$ of all engineering graduates are located in these areas. The question naturally arises as to the educational facilities, activities, and future needs of these areas. In the development of plans it would seem fairly fundamental to make a scrutinizing study of each district, bearing in mind the achievement of the fundamental objective of providing variety in training along with opportunity for professional development.

The successful development of facilities appropriate to each area, although depending largely upon the educational leaders of established institutions, will likewise need the support and cooperation of industries; at least to the extent of their making known the nature of their employment and training requirements, and stimulating their employees to take advantage of such educational courses as may exist. It would seem that the establishment of a well balanced program should include:

1. A study of the nature of the industries and occupations in the area considered.
2. Promotion of an effective system of vocational training in addition to academic high school education.
3. Establishment, where justified, of appropriate facilities for intermediate technical instruction of both the technical high school and the institute type.
4. Development of existing professional engineering schools.

The importance of a well balanced program is recognized, of course, but in only a few instances has any particular attention been given to the technological aspects of it.

### New York Studies

In New York 2 significant studies are in progress: one conducted by the Board of Education has to do with vocational education; the other is entirely independent, and is concerned primarily with evening technical education. The latter study is being conducted by the committee on commercial education of the Chamber of Commerce of the State of New York. A full report of this survey will be published in the fall of this year and should prove of interest to educators and industrialists. The main objective of the report is to ascertain the facts concerning the present facilities for adult technical education in the New York industrial area, and the purposes, results, and needs for education in this field.

### New York Educational Facilities

The 1930 census established the New York industrial area as including a population of 10,901,424, or slightly less than 9 per cent of the total population of the country. For the purposes of the Chamber of Commerce survey, the area considered is approximately the same as this district and includes 6 counties in New York and 6 counties in northeastern New Jersey.

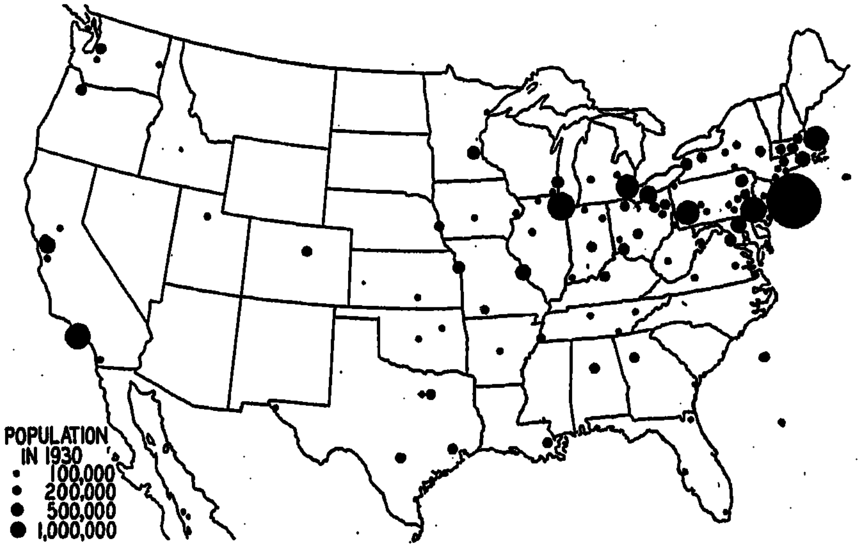

**Fig. 2. The 95 "metropolitan" districts listed by the U.S. Department of Commerce based upon the 1930 census**

In this area the schools and colleges giving some form of education associated with or preliminary to technical instruction include 12 engineering colleges and technical institutes of which 9 offer evening instruction, 4 evening schools of the Y.M.C.A. offering technical instruction, 25 public evening trade and vocational schools, and 32 private evening trade and vocational schools. The 9 engineering schools or institutes offering evening instruction are the agencies for primary consideration.

### Enrolment in Evening Technical Courses

In the 9 colleges and technical institutes offering evening courses approximately 10,000 students are enrolled; another 25,000 are enrolled in either trade or vocational schools. The distribution of enrolments by courses is shown in Table I, and may be taken as an indication of the relative demand.

Of special interest is the group of students enrolled in the 9 colleges and technical institutes. The 13,660 course enrolments studied covered only 8,000 of the 10,000 students enrolled, but were so taken as to be representative of the group. An effort was made in the survey to study the type of students enrolled, and their industrial employment. About $^2/_3$ of the students were found to be between 19 and 26 years of age, although it is significant also that many were men occupying substantial positions in industry.

A study of the educational preparation of these students indicates that about 80 per cent had a high school education or better, about 33 per cent had gone to college, whereas less than 10 per cent were college graduates. This latter figure, while small in comparison with the entire group, represents from 800 to 1,000 college graduates, and is evidence of considerable interest in further education.

## GRADUATE STUDY

Up to the present school year the only evening colleges offering recognized degree-granting courses in engineering were New York University, The Polytechnic Institute of Brooklyn, and the College of the City of New York. These courses require from 6 to 10 years for completion. Only one of these schools, The Polytechnic Institute of Brooklyn, offers degree-granting postgraduate courses. The development of this work by the Polytechnic Institute is of considerable importance, for many college graduates yearly find employment in the New York area and look for opportunity for further study there. Prior to 1925 only a few miscellaneous courses of the graduate level were offered at Brooklyn Polytechnic Institute.

The development of evening graduate study doubtless will be followed with considerable interest, for it suggests an effective means for the engineer to continue his education after graduation, and offers also a solution to the economic problem of financing graduate study after a considerable investment already has been made for undergraduate work.

## NATURE OF NEW YORK INDUSTRIES

In a metropolis such as New York the question of the adequacy of local technical education is advanced periodically, either by civic associations, educational bodies, newspapers, or other interested groups. A suitable approach to the answer to questions relating to demand, utilization, and encouragement of technical graduates would seem to be a systematic investigation of the industries in each of the large metropolitan areas, with the objective of establishing or developing such educational agencies as seem necessary to meet industrial requirements.

In most industrial concerns the most important requirement is to impart to the individual sufficient technological information about the process he handles to enable him to conduct his work intelligently. Because such training usually takes the form of single process instruction to the individual, it is not concerned with education of college or professional grade. It is a serious question, however, as to how much technological instruction can and should be given technical workers and minor supervisors. Since technical instruction is an instrument of industry and its place and usefulness is confined almost entirely to industry, there would seem to be a field in technical education which should aim to supply such scientific courses as would aid the individual to a better understanding of technical processes. What these subjects are must evolve largely from a study of industry.

New York is commonly looked upon as an area of large industrial establishments. However, the fact is that aside from about 3 dozen large manufacturing companies employing on an average 2,233 employees, and a group of 1,700 companies of intermediate size employing on an average 292 employees, each of the remaining 34,000 companies employ less than 100 individuals, and average only 16 per establishment. The large manufacturing companies employ only $6^1/_2$ per cent of the total; and the small companies 50 per cent. These facts would seem to indicate considerable difficulty in training substantial numbers within industry, and almost a necessity for some outside agency to provide technological training either prior to the individual's employment or through evening education for those employed.

In connection with New York evening school enrolments it is of interest to observe that fully 3 times as many students are enrolled from the service industry group as from the manufacturing industry, although the latter employees number almost 50 per cent more than service industry employees.

The service industries include public utilities, city employees, architects and consulting engineers, building industries, cleaning establishments, and garages. The public utilities are large, well established companies with training requirements for the most part cared for internally. Their employees, however, in comparison with those of the manufacturing group, seem to show more interest in professional technical courses, as do also the employees of the city and professional engineering establishments. This manufacturing group looks more to the professional schools of engineering for recruiting its future technical personnel.

## DEMAND AND NEED FOR TECHNICAL EDUCATION

From preliminary observation it would seem that there is need for variety in technical education; and that the development of adult or evening instruction in metropolitan areas offers a partial solution in meeting the need not only for the intermediate type of training, but also for the graduate instruction of the engineer. This is a subject of interest to all of us. However, the demand as manifested by the interest of employees in industry is not so evident. This may be due to any or all of the following causes:

1. Facilities are not always conveniently available.
2. The proper incentive has not always been given through definite educational and training policies on the part of management.
3. Unit courses are not developed sufficiently for maximum benefit to the employee.
4. Anything less than the conventional 4-year college course seems not quite reputable nor acceptable to those to be trained, perhaps because of the feeling that such training might limit their life achievement to specific fields and levels less remunerative and esteemed than those attained through the 4-year college course.

From an industrial point of view, there is little or no justification for the latter conclusion, for in the industrial and service group in the New York area alone, there will be in the next 10 years at least 150,000 positions of suitable responsibility available. How many of these should be occupied by technical graduates is not known, but it is safe to say that the majority of them will be filled by men of less than college graduate training, whose chances would be greatly improved if they were in training today.

This article is presented for the purpose of calling to attention a possibility which if followed to a logical conclusion, holds promise not only of improving the professional status of the engineer, but also of causing a more sane adjustment of technical workers to acceptable vocations. In its fundamentals it means a study of the world's work and the acceptance of the philosophy of the concurrent pursuit of educational improvement and gainful occupation.

---

# Double Conductors for Transmission Lines

**Two overhead conductors a few inches apart used for each phase of a transmission line circuit reduce the reactance 20 per cent or more, thus, in many cases, increasing the power rating of the line. Also current carrying capacity and corona voltage limits are increased. However, costs with this type of construction are higher than with one larger conductor per phase. In addition to describing the advantages and disadvantages of double conductor lines, formulas are given in this article for the calculation of the electrical characteristics.**

By
H. B. DWIGHT
FELLOW A.I.E.E.

E. B. FARMER
NON-MEMBER

Both of
Mass. Inst. of Technology,
Cambridge, Mass.

DOUBLE conductors transmission lines, that is, lines employing 2 overhead conductors for each phase instead of the usual one for each phase, present a number of advantages. These advantages must be balanced against the extra cost due to mechanical features, including hangers, increased cost of stringing and additional wind and ice load. The construction is the same as in the usual transmission line except that a second conductor is run a few inches below the first by metallic hangers, similar to those used in electric railway catenaries. The 2 conductors therefore are electrically in parallel and form one effective conductor of large cross-section without increasing the number of insulators or crossarms.

## REACTANCE

An overhead double conductor line has approximately 20 per cent less reactance than a single conductor line of the same weight of conducting metal. In many usual cases, especially where there is not complete control of the voltage by synchronous condensers, the reactance is the most important item in determining the power rating of the line, for both the voltage drop and the stability limit of the load

---

Based upon "Double Conductors for Transmission Lines" (32-99) presented at the A.I.E.E. North Eastern District meeting, Providence, R. I., May 4-7, 1932.

depend principally on the reactance. Therefore, in many instances, without increasing the weight of conductor metal, a line can be built for about one-fifth greater power rating at very little increase in cost where ice load is absent, by using double conductor construction. This is particularly advantageous where the cost of the right-of-way is large, and is is desirable to transmit as much power per circuit as possible.

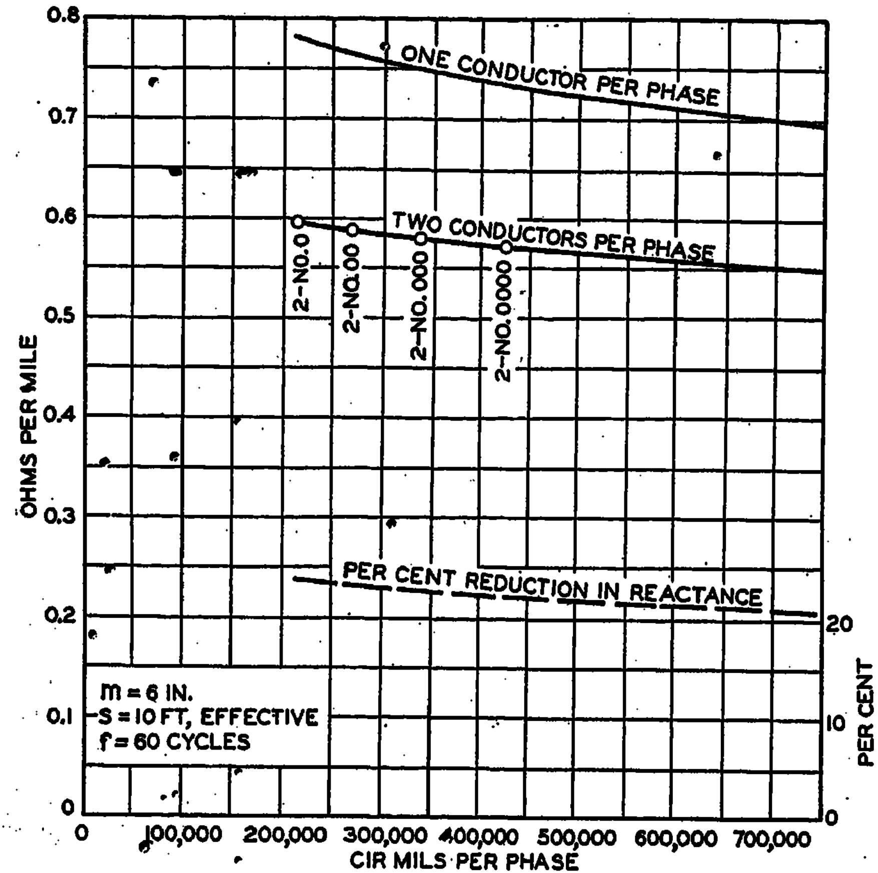

**Fig. 1. Comparison of reactance of single and double lines for different conductor sizes**

In Fig. 1 is shown graphically the reduction in reactance, amounting to approximately 20 per cent on practical lines, obtained by using double conductor construction. The formula for the reactance of a double conductor line, suitable for usual overhead spacings and for round wire, is

$$\text{Reactance} = \pi f 10^{-6}\left(80.5 + 741 \log_{10}\frac{s^2}{m\rho}\right) \text{ ohms per mile} \qquad (1)$$

where

$f$ = frequency
$s$ = geometric mean radius of the spacings between the phases
$m$ = separation of the 2 wires per phase
$\rho$ = radius of the conductors

If the conductor is a 7-strand cable of diam $2\rho$, the figure 80.5 is changed to 103.3 and if there are 19 strands, the figure becomes 89.3. (See reference 9, p. 127, for other numbers of strands.)

Fig. 1 is drawn for copper conductors. It may be noted that hollow conductors and aluminum conductors of equivalent resistance have from 5 to 7 per cent less reactance than the values shown for single conductors in Fig. 1. The 2 small conductors of the double conductor line may be of aluminum if desired.

The effect of changing the distance between the 2 wires of the same phase, in a double conductor line, is shown in Fig. 2. It is seen that for spacings larger than 6 in. there is little further improvement. Accordingly the discussions in this paper for the most part are based on a value of 6 in. Curves for other conductor sizes and for other spacings between phases are very much the same as the curves of Fig. 2.

## Resistance

Another limit to the power rating of a transmission line is the cost of resistance losses. The greatest advantage of double conductor construction in this connection is in the case of a line already built, which has higher resistance than desired and which has some mechanical margin of safety. It is possible to add a second conductor and cut the resistance in half without the necessity of taking down or scrapping the old conductor. In other words it is possible to make the reduction in resistance with only one-half as much new conductor metal as would be needed if single large-size conductors were installed. It is, of course, necessary that the line be strong enough to stand the extra weight including wind and ice on the second conductor. The proposition to add to the conductor metal of existing lines may be attractive at a time when the cost of conductors per pound is low.

For new transmission lines the difference in resistance between single and double conductor lines of a given weight of conductor metal is due to skin effect. The amount of the difference is shown in Fig. 3. It is seen to be a matter of minor importance with overhead conductors of usual sizes. For obtaining values of skin effect of hollow conductors, see reference 1.

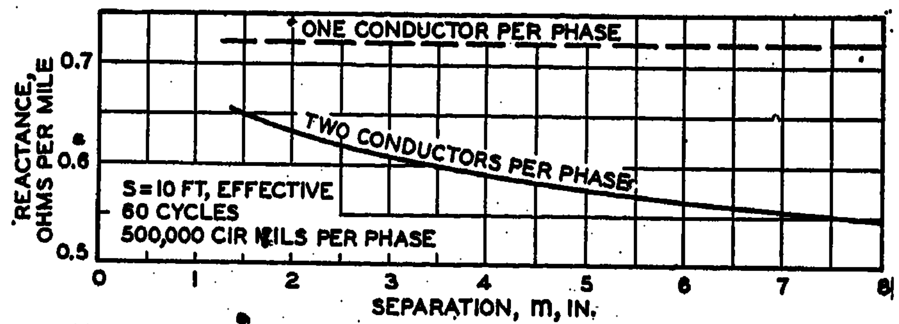

**Fig. 2. Change of reactance with separation of paralleled conductors**

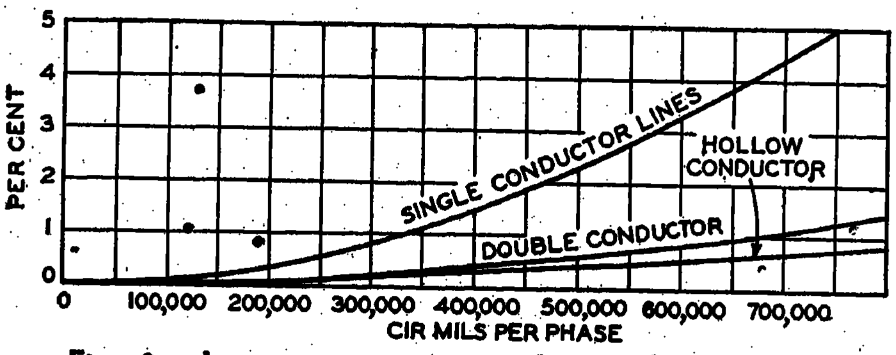

**Fig. 3. Increase in resistance due to skin effect at 60 cycles**

## Heating of Conductors

In the preceding 2 paragraphs the cost of resistance losses was considered as a limitation to the allowable power load of a line. With some short lines, and notably with many tie-lines, voltage drop and the cost of resistance losses are not serious limitations to the allowable load, and heating of the overhead conductors is the practical limit encountered. In many cases, twice the normal load must be carried by one circuit as an emergency condition. Annealing of the hard-drawn copper and oxidation of joints in connectors are reasons for keeping the conductor temperature down.

Tie lines have been built with very heavy overhead conductors for the purpose of avoiding overheating of the conductors. A 132-kv, 30-mile tie line from Chicago, Ill., to Waukegan has been built with 750,000-cir-mil hollow copper conductors. It is stated in reference 6 that the main condition in designing the line was the heavy current to be carried.

The curves of Fig. 4 have been drawn from the table of current ratings published in reference 3, p. 466, for bare conductors, outdoor service, and 40 deg C rise. It is seen that double conductor construction increases the current carrying capacity nearly 30 per cent for a given weight of conductor metal. This is because the 2 small conductors have more surface than the single large conductor. If current ratings from the table for indoor service were used, the percentage difference between single and double conductor construction would be nearly the same. Hollow copper conductors, because of their large diameter, show an increased current carrying capacity over corresponding standard cables, though the increase is usually a small percentage. Aluminum conductors also have larger diameter and therefore greater current carrying capacity than standard copper cables of the same resistance.

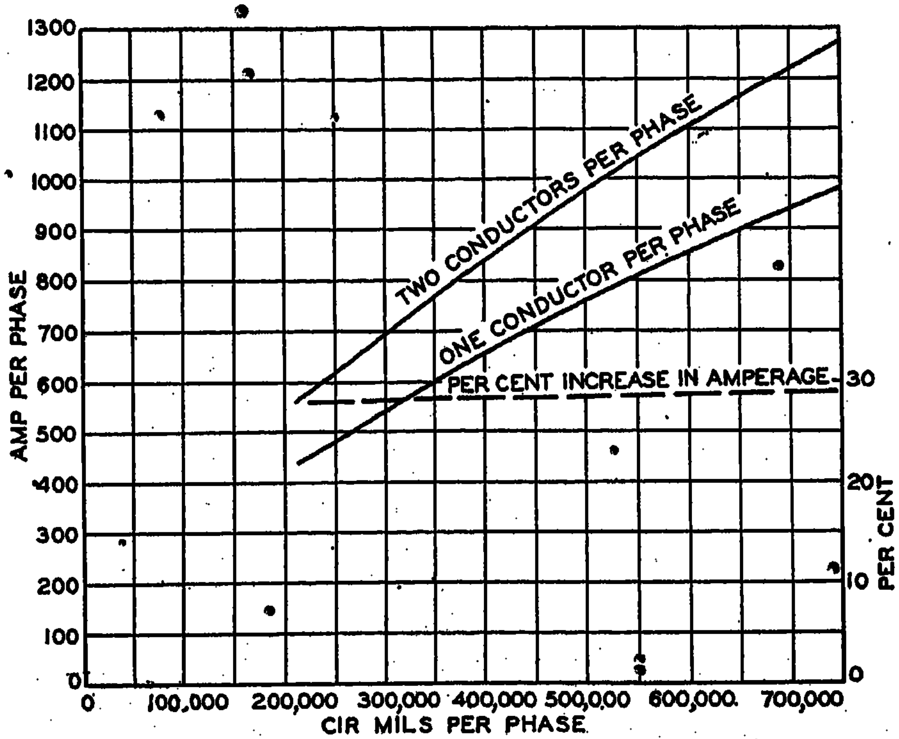

**Fig. 4. Current carrying capacity of bare conductors for outdoor service with 40 deg C temperature rise**

CAPACITANCE

As is shown by Fig. 5, the capacitance of an overhead double conductor line is 20 per cent or more greater than that of a single conductor line of the same weight of conductor metal. This is an advantage in the case of power networks in well-settled parts of the country where the loads and generating stations are scattered to some extent throughout the network. In such networks it is a matter of experience that synchronous condensers are used almost entirely with strong field currents, and very few with lagging power factor load and weak field currents. Consequently, an increase in line capacitance of 20 per cent means a saving of a definite amount of synchronous condenser capacity which would otherwise need to be installed.

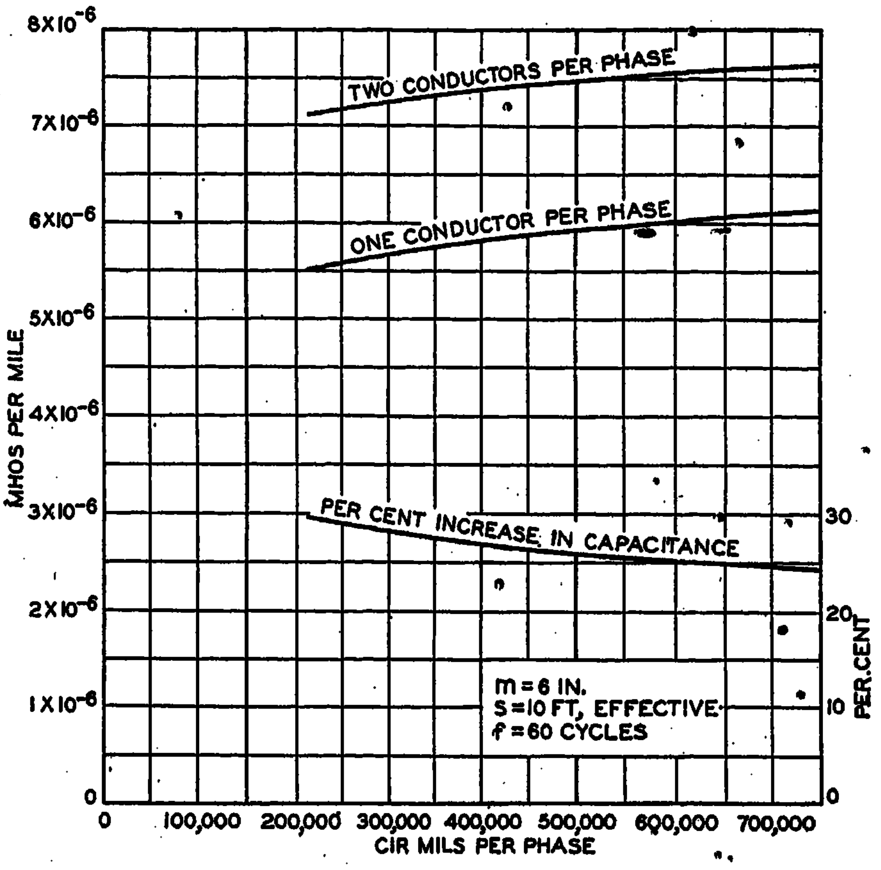

**Fig. 5. Comparison of capacitive susceptance of single and double conductor lines**

In other cases, where transmission lines are very long and the loads are widely separated from the generators, special attention is required to handle the line capacitance current. A sufficient number of generators must be kept always connected to the system, so that the no load current is not an overload for them and so that the field current at rated voltage and leading power factor load does not become so small as to endanger the stability of the system. While these matters require attention, yet they seldom involve expense, particularly in the case of water power systems where they are most likely to be noticeable, for there are practically always plenty of generators available. Accordingly even in such cases an increase in line capacitance by using double conductor construction is not an economic disadvantage.

The formula for capacitive susceptance of a double conductor line of usual capacity is

$$b = \frac{4\pi f\, 38.8 \times 10^{-9}}{\log_{10} \dfrac{s^2}{m\rho}} \text{ mhos per mile} \qquad (2)$$

CORONA

Values of corona voltage, that is, the voltage at which corona starts, are shown in Fig. 6 for 1 and 2 conductors per phase, where $m$, the separation of the 2 conductors of the same phase, is 6 in. Very little increase in corona voltage is obtained by using 2 small conductors of the same type as the single large one. This is in general true at separations other than 6 in. More increase in corona voltage is obtained by using 3 or more conductors per phase. The use of a hollow or cored conductor gives a considerable increase in corona voltage.

Measurements of the corona voltage with 2 and 3 transmission line conductors per phase are given in reference 8, p. 82, and also in the first edition of the same book, published in 1915, p. 71 and 72.

If a double conductor line and a single conductor line have the same calculated corona voltage, the operating voltage of the double conductor line should be kept lower than that of the other, because when corona does start, as in stormy weather, the double conductor line has twice as many conductors on which loss takes place.

The formula for corona voltage of a double conductor line of usual spacing, assuming an average irregularity factor $m_0$ of 0.85, is

$$e_o = 105\,\rho \log_{10} \frac{S}{\rho} \qquad (3)$$

A number of features relating to the use of 2 and 3 conductors per phase are discussed in reference 7. In this work a rather large spacing between the paralleled conductors, namely 18 in., was assumed.

## Mechanical Features and Costs

A transmission line with 2 conductors per phase could be constructed using a type of hanger already developed and tried out for electric railway catenaries. It would be more expensive than a single conductor line of equal mechanical strength. The duty on the towers, and their height, would be greater due to approximately twice as much wind and ice load. More clearance would be required and shorter spans might be needed. More margin of safety would be required in the tensile strength of the conductors, for although each might be pulled up to the proper tension, it would not be certain that one conductor would not take more than its share of the tensile load at some later time. The cost of stringing the conductors would be greater. Since the increase in ice load is perhaps the greatest disadvantage, the use of double conductors is of most interest for southern districts, where ice load is not encountered.

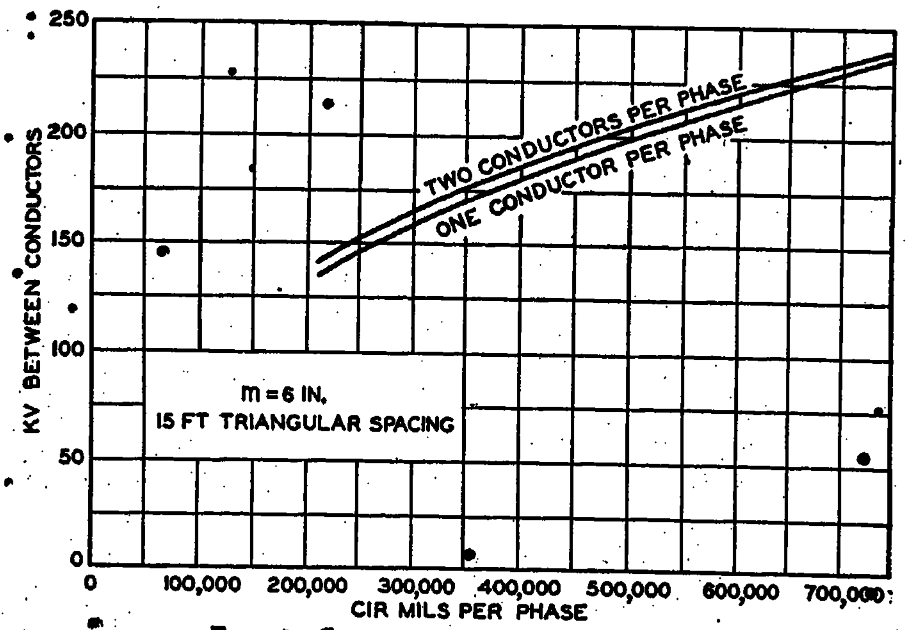

Fig. 6. Corona voltage at sea level

The additional cost due to the mechanical features of the double conductor construction is to be balanced against the value of the advantages to be obtained. If circumstances are such that the voltage drop in the line must not be more than a certain percentage, then 20 per cent reduction in reactance permits a corresponding increase in the allowable power load. In such a case the additional cost is to be compared with 20 or 25 per cent of the entire cost of the transmission line. This assumes that methods of controlling the voltage, as by synchronous condensers, are not considered applicable, and that the only way in which the power can be increased is by decreasing the reactance or providing additional circuits.

An increase in current carrying capacity or in corona voltage might be an additional advantage, but such an increase would probably not by itself justify the special construction, for ratings now in use. The current carrying capacity or corona voltage of a single conductor line could usually be increased 30 per cent without increasing the cost of the entire transmission line more than a few per cent, by using a heavier conductor or one of about 30 per cent larger diameter. The cost of the conductors is only a fraction of the cost of the entire line. Such a conductor, however, will not give 20 per cent less reactance. The large reduction in reactance is therefore the most important feature of the double conductor construction.

In conclusion, the advantages shown are as follows: Approximately 20 per cent less reactance; the opportunity in some cases to add to the conductivity and power rating without scrapping the old conductors; the almost entire elimination of skin effect; and the increase in current carrying capacity of nearly 30 per cent. The disadvantages are the greater clearance and mechanical strength required, particularly where ice load is important, the cost of hangers, and the increased cost of installation.

# The Significance of Noise Measurements

**Dirt has been defined as being matter out of place; likewise noise may be regarded as misplaced sound. Sounds that are attractive musical notes under one circumstance may be distressingly annoying under other conditions. Present knowledge of noise and its effective control is summarized here.**

By
KENNETH H. PRATT
General Elec. Co.,
West Lynn, Mass.

SOUND is a general name for anything that is heard including music, speech, and various kinds of noise. The word "noise" implies annoyance, and includes: such separate disturbances as hammer blows, footsteps, or the slam of a door, many sustained tones which would be considered under some circumstances to be musical, the complex sounds emitted by almost all kinds of machinery, and music and speech when considered as a disturbance of the hearing sensation (that is, when the reception of that particular music or speech is not desired by the listener).

"Noise" also refers particularly to the complex disturbance caused by a group of people talking independently, as an audience does before a meeting is called to order, or any other complex jumble of disturbances perceived by the sense of hearing. In factory or office buildings there is a surprising amount of this complex disturbance which is the combined effect of people talking and moving about, various pieces of machinery operating in different parts of the building, the operation of typewriters and ventilating fans, water running in pipes, and so on. In a busy street there is much noise of this sort, the effect of many different causes.

## Simplest Sound a Pure Tone

The simplest sound is what is known as a "pure tone." A pure tone has both intensity (amplitude) and frequency (pitch), and consists of a regular motion of the particles of air which lie between the source and the listener. By virtue of this motion the pressure of the air at any particular point becomes (many times per second) alternately greater and less than the average. The frequency of this alternation is the frequency or pitch of the sound. To be strictly accurate, the manner in which the pressure changes at any point as a function of time must be what is known as sinusoidal variation if the tone is to be a pure tone.

If the variation of pressure with respect to time is not sinusoidal and yet is regular to the extent that the complete mode of variation is continuously and exactly repeated (many times per second) the sound is what is called a "musical tone." The effect is the same as if several pure tones (each having a frequency which is a multiple of the fundamental frequency) were produced and heard simultaneously. When such an equivalent set of pure tones is identified, the "musical tone" is spoken of as having been analyzed into its components—the "fundamental" and the "harmonics." The difference recognized when the same "note" is played on different musical instruments arises from the different wave shapes or modes of vibration of the air when set in motion with the same fundamental frequency by the different instruments. This usually is expressed by saying that different instruments have different timber or quality or that they give rise to tones in which the different harmonics (or overtones) differ in strength.

The noise emitted by some machinery may be practically a "musical tone" as that term has just been defined. Many machines, however, emit noises which are the equivalent of several simultaneous "musical tones." The fundamental frequencies of these several components may bear no simple relation to one another, and the result is what would be called discord in music; but this aspect of the matter perhaps is overshadowed in the mind of the listener by the effect of the persistence or repetition of the particular combination of sounds, a disagreeable effect never attempted in music.

Music and speech, when regarded as noise, differ from the noises usually made by machinery in that they change rather rapidly their characteristics of frequency and amplitude. That is, during the brief time that any particular note (in music) is being held, or for the duration of a particular sound such as a vowel sound (in speech), the sound may be analyzed into component "pure tones"; but very soon, as the music goes on to the next note or the speech goes on to the next speech element the set of component pure tones is changed. During the transition from one note to another or from one speech element to another the motion of the air particles may not at all correspond to periodic motion.

If many people are talking at once the number of frequency components in the resulting noise becomes so great that, so far as the analytical apparatus of the ear (or of most physical measuring apparatus) is concerned, components of *all* frequencies over a wide range are present. Of course the detailed conditions change rapidly, but if the number of voices involved is large there is established a sort of dynamic equilibrium which is registered by the ear as a fairly constant noise. Conditions similar to this may arise from other causes. The noise of "air rush" from a fan or near any rapidly moving piece of machinery, apparently because of the rapidly shifting arrange-

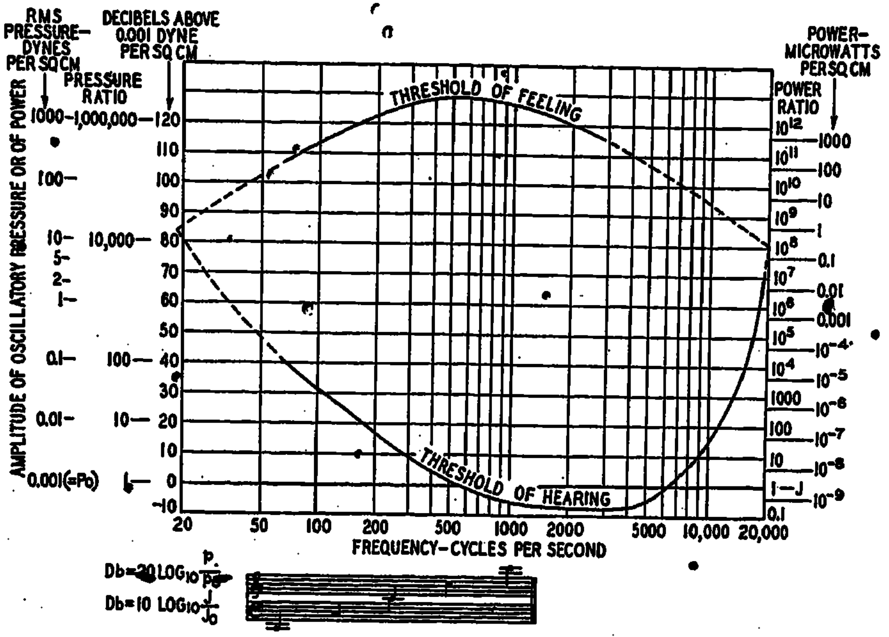

Fig. 1. Range of auditory sensation for the average human ear

ment of air eddies, seems to have this characteristic of indefinite frequency. Such a noise of course may include or be accompanied by component tones of perfectly definite and sustained frequency.

### Range of Human Perception

The "auditory sensation area" of the average human ear is shown in Fig. 1 where the abscissae represent frequencies plotted on a logarithmic scale. It may be noted that tones having frequencies anywhere in the range from 20 to about 20,000 cycles per second may be perceived by the ear. The limits differ widely for different individuals and there is a tendency for the upper limit to be reduced with increasing age of the observer.

Frequencies are plotted on a logarithmic scale for two reasons: (1) it accommodates conveniently the extensive range of frequencies involved, and (2) on such a scale the musical intervals such as octaves, fifths, and so on, which appear to have a rather fundamental importance in human comprehension of sounds are represented as equal intervals regardless of frequency. That is, the interval from 100 to 200 cycles per second is an "octave" as is also the interval from 2,000 to 4,000. The note represented in musical notation as "middle C" has a fundamental frequency just a little above 250 cycles per second.

The ordinates of Fig. 1 are values of the physical amplitudes of the tones at the ear of the listener. These may be indicated in several different units and may be expressed in terms of the pressure variation of the air or in terms of the power transmitted. The striking fact is the extreme range of amplitudes which may be perceived as sound, a range in the order of a ratio of 5,000,000/1 in terms of pressure variation or of $10^{13}/1$ in terms of power. For a diagram such as this to cover such an extensive range it is practically imperative to plot the values logarithmically, as has been done here. It is convenient in the practical work of measuring noises to refer to their amplitudes by a logarithmic scale such as the "decibel" scale. The "bel" or the "decibel" is fundamentally a unit of power ratio, and when used to state the amplitude of a noise the reference value of power (or the corresponding pressure variation) must be expressed or implied.

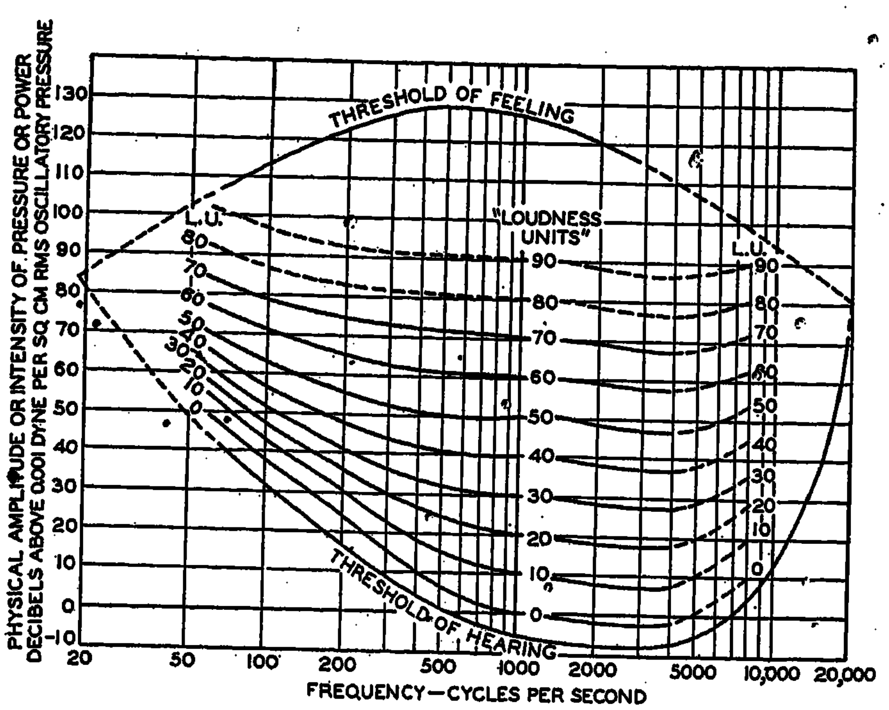

Fig. 2. Area of average human auditory sensation showing "equal loudness" contours

As a unit of noise measurement the decibel (db) has the practical advantage of being roughly the minimum change of amplitude which ordinarily can be detected, considering the whole range of audition. It is not by any means a perfect fit in this respect, but it is much better than any non-logarithmic unit would be.

### Comparison of Loudness

Figure 2 shows what are called "equal loudness contours" for pure tones. If a listener be asked to observe the difference in 2 different pure tones sounded one after the other he probably will be more conscious of a difference in frequency (pitch) than of a difference in loudness. This is because of our training, and the habit of associating noises with their sources. Noise is observed from a given source under widely varying conditions of loudness depending upon the distance from the source and upon the amount of absorbing material such as room walls between the listener and the source. The frequency of a note from a given source is subject to much less variation. It is the frequency of the noise, then, that is the more important clue to the interpretation of noises heard. (Usually complex sounds rather than simple tones are heard and the habitual association of sound with source depends upon several frequency components being heard simultaneously.) However, it is possible to decide which of 2 tones sounds the louder, provided there is sufficient difference between them, even though the 2 tones be of different frequencies.

From another point of view, given the proper physical equipment for producing sounds of varying amplitude, it is possible to make a sound which seems as loud as a 1,000-cycle tone of standard loudness. The "equal loudness contours" in Fig. 2 connect points representing tones which, from the average results of many such experiments, seem to impress the average observer as being of equal loudness.

Hence the position of a plotted point relative to these loudness contours is an indication of what may be called the "physiological loudness" of the corresponding tone. A numerical value may be given to the physiological loudness of a tone of any frequency by stating the physical amplitude of an equally loud tone of some standard frequency, say 1,000 cycles per second.

A musical tone, machinery noise, or other complex noise can be assigned a value for loudness in essentially this same manner by comparison with a pure tone of standard frequency adjusted to equivalent loudness and measured for physical intensity. This leads to the definition of the "loudness units" of any noise as the "decibels above 0.001 dyne per sq cm (rms oscillatory pressure)" of a 1,000-cycle pure tone which appears equally loud when the 2 sounds are compared. It would be very difficult to determine the loudness of an ordinary noise if a *direct* comparison really were required. The "noise meter" in effect makes this comparison, but what it actually measures is the amplitude of all the noise components, integrating their effect after weighting them according to their frequencies and the experimental data on equivalent loudness, considering the components as pure tones.

From a practical standpoint it is more important to know how annoying a noise from a certain source will be rather than to know how loud it is. This question goes beyond both the physical considerations of noise and the physiological question of loudness; it is a complex psychological question. Apparently the annoyance of a noise depends upon the loudness of its components and in a complex way upon their frequencies. Annoyance also depends upon circumstances, such as whether the noise seems the normal accompaniment of the work in hand or is distracting. A carpenter probably gets some sort of satisfaction out of a good clear "bang" each time he hits at a nail with a hammer whereas a disinterested neighbor may be severely annoyed by the same sound.

Reduction of the amplitude of the loudest noise components in a complex noise may be presumed to reduce the annoyance caused by that noise. The relative annoyance of two complex noises having different frequency components, such as the noises coming from motors of different design, involves questions of "masking" of one component by another, questions of discord between the several components, and questions concerning the relative annoyance of the different components considered as pure tones. Incidental observations made in the course of various noise investigations indicate that pure tones annoy different observers in a very different manner, considering annoyance as a function of frequency. However, that is a complex matter of psychological research which so far has not been investigated comprehensively.

## SOURCES OF NOISE

In considering briefly its production and distribution, sound, in the physical sense, may be considered as one form of power, quantitatively microscopic, transmitted through the air and other media. Usually the immediate source of the energy transmitted to the air is the mechanical vibration of some surface, such as the sounding board of a musical instrument or the vibrating surfaces connected with a piece of machinery. The discovery of the "cause" of a noise usually implies some further explanation of the connection between the vibrating surface and some more fundamental source or energy. A satisfactory explanation of a noise requires a knowledge of the fundamental energy source, the mechanism of transformation into vibration, and the means by which the vibration is transmitted to a definite "sounding board."

## NOISE MEASUREMENTS

Included in the term "noise measurements" are several different measurements including the determination of: the physiological value for "total noise," in "loudness units"; the frequencies of the principal components of the noise; and the physical amplitude or the equivalent loudness of the several noise components. Also, the closely related measurements of frequency and amplitude of mechanical vibrations involved in noise production may be included in the category of noise measurements.

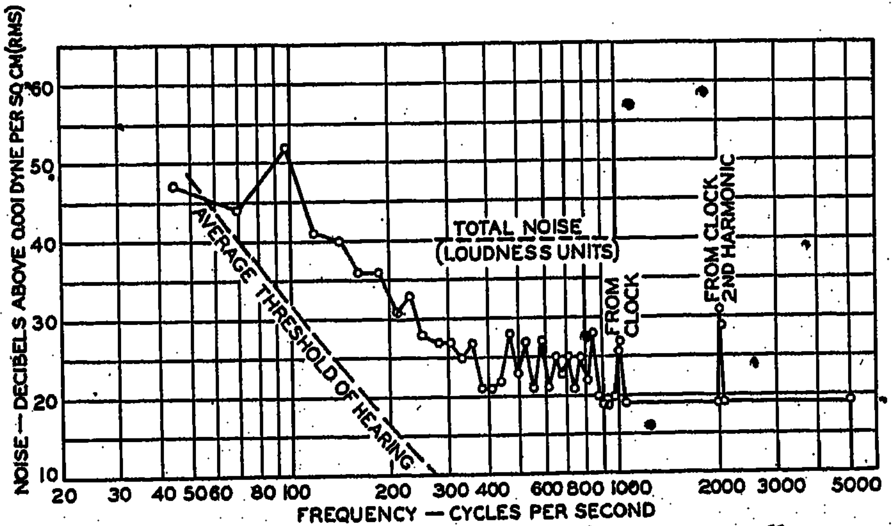

**Fig. 3. Analysis of room noise in a laboratory office**

The weighting to compensate for the differing response of the ear to different frequencies makes the "total noise" as measured in loudness units less in this case than the maximum noise as expressed in decibels. Readings were taken arbitrarily at each division of the analyzer frequency dial

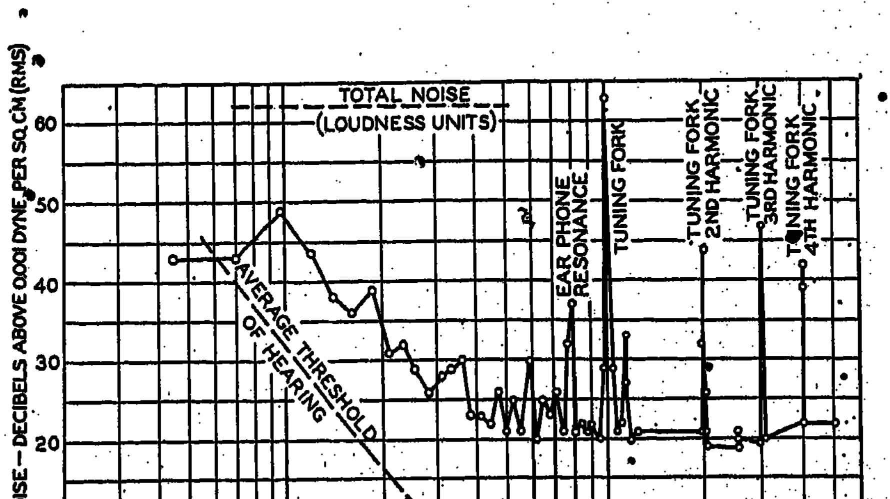

**Fig. 4. Analysis of the room noise of Fig. 3, as augmented by sounds from a 1,000-cycle tuning fork**

Results of noise measurements made in one particular room are shown in Fig. 3, plotted logarithmically the same as for the first 2 figures, except that the scale is somewhat larger and only a part of the auditory sensation area is shown. The noise in this case consisted largely of a jumble of various low frequency noises none of which were constant. The noise as a whole is equivalent in loudness to that of a 1,000-cycle tone of an intensity 40 db above 0.001 dyne per sq cm; that is, the noise is one of 40 loudness units. Because of the weighting of the total to compensate for the different sensitivity of the ear for different frequencies, the "total" is less in loudness units than some of the indefinite low frequency components as measured in decibels. The 2 small components of definite frequencies (1,000 and 2,000 cps) were readily identified as coming from a nearby clock connected to a piezoelectric standard for radio frequencies.

After observing the measurements of room conditions as shown in Fig. 3 further readings of the noise level were made at the same place after starting an electromagnetically driven tuning fork, the sound of which was brought to the vicinity of the microphone by means of a telephone receiver. This superimposed noise simulated a very simple machinery noise and produced the effects shown in Fig. 4 where it may be noted that the low frequency jumble remained practically unchanged. The definite noise component occurring at 800 cps arose from the fact that the telephone receiver was designed for resonance at 800 cps. At 1,000 cps may be noted the fundamental note of the tuning fork, and at 2,000, 3,000, and 4,000 cps, respectively, the second, third, and fourth harmonics of the tuning fork note. The "total noise," which consisted principally of the 1,000-cps tone, may be noted to agree rather closely with the physical amplitude of that component.

Obviously the values obtained in these measurements depend not only upon the source of the noise, but also upon the relative positions of the measuring device (the listener) and the noise source, particularly if the latter be a complex piece of machinery. Less evident, but nevertheless true, the amplitude or loudness of a noise depends upon other surrounding conditions such as the sound reflecting characteristics of walls and furnishings, and the manner in which the source of noise (such as a machine) is supported.

"Noisiness" undoubtedly is a characteristic of certain machinery, but its measure in comparable physical units requires carefully detailed specification of the many relevant conditions. In many cases "noisiness" probably is not a fault of any one of the several pieces of machinery involved in a specific case but rather the result of unfortunate chance relationships within the group.

Noise measurements are beginning to be used as a basis for standards of acceptable "quietness" for certain products. Noise measurements provide the principal means used in all efforts to reduce noise; they are effective because:

1. They establish standards by which the effect of changes may be compared, whether the changes be of design of equipment, operating conditions, or even legal restrictions. The ear, used directly, not only is inaccurate, but is terribly misleading unless a *direct* comparison of two noises is to be made.
2. Noise measurements aid in detecting "sounding boards" in complex apparatus. Design changes of these parts or the application of sound absorbent material reduce the noise.
3. Measurements of noise and vibration frequencies are effective because they usually indicate the fundamental source of the sound energy.

Once the mode of production of a noise is understood its reduction may be accomplished relatively easily by reducing the primary driving impulses, by interfering with the transmission of power between its source and the sounding board, by changing the physical characteristics of the sounding board, or by intelligent application of sound absorbing material.

# Transmission Towers Span Railway Tracks

**Transmission lines are carried into the city of Milwaukee, and through adjacent territory, on railway rights-of-way. Special towers have been developed to span the tracks in the more highly congested districts, and studies have been made to indicate which type of tower is the most economical.**

Both of
Milwaukee Elec. Ry. and
Lt. Co., Milwaukee, Wis.

EXISTING rights-of-way of the interurban railway system are utilized where feasible for the location of transmission towers for the 132-kv and 66-kv lines of the Milwaukee Electric Railway and Light Company and its associated companies. As a result of this practise, 4 different types of tower line construction have been developed. They are as follows:

1. Standard square base towers
2. Two-track bridge type towers
3. Vertical side bridge type towers
4. Four-track bridge type towers

---

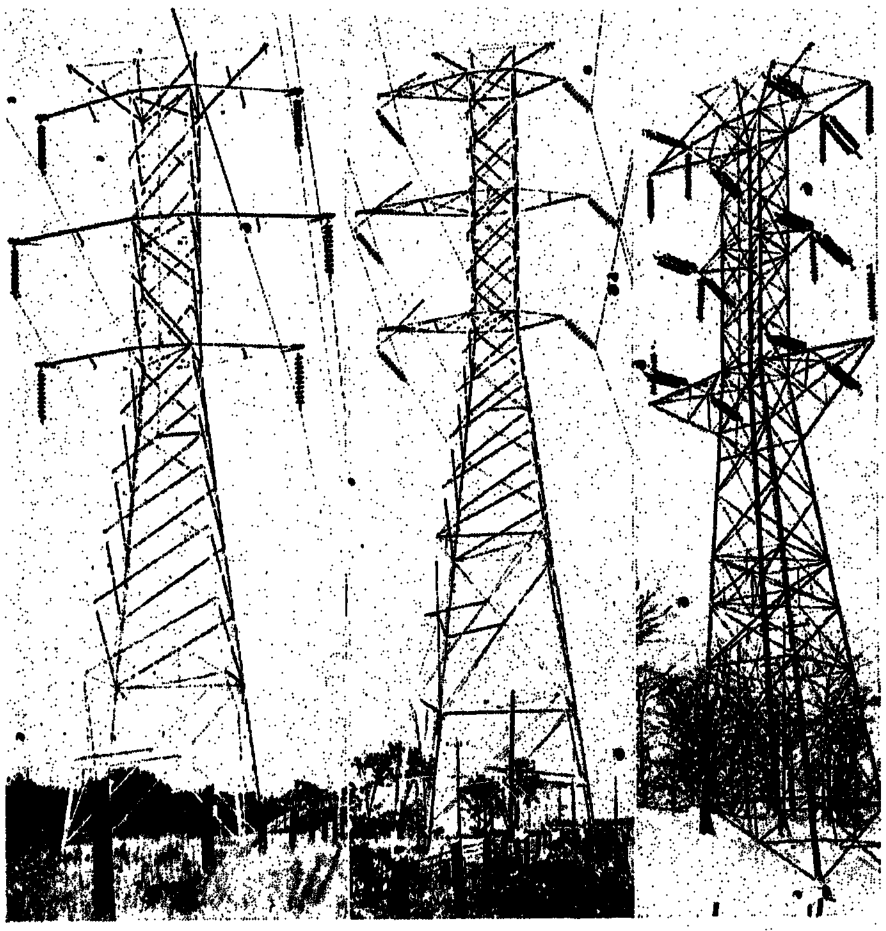
Based upon "The 60-Cycle Primary Transmission System of the Milwaukee Electric Railway & Light Company and Associated Companies in Wisconsin and Upper Michigan" (No. 32M3), presented at the A.I.E.E. Great Lakes District Meeting, Milwaukee, Wis., March 14-16, 1932.

The latter 3 types are used on railway right-of-way where the width available does not allow the use of the standard square base towers. The conductors in these cases are carried in part or entirely over operating tracks. In addition to the high-voltage transmission line conductors, these towers carry the railway catenary construction, supply feeders, and signal circuits. Provision is made also for the installation of from 2 to 4 medium voltage transmission lines.

The primary transmission system, operating at 132 kv or 66 kv, is used to transmit bulk energy from the generating stations to step-down substations, and to interconnect the Milwaukee system with hydroelectric plants in the northern peninsula of Michigan. The capacity of 132-kv transmission lines from 2 of the generating stations, near Milwaukee, to the various substations in the Milwaukee area, has been standardized at 90,000 kva; 300,000-cir mil copper conductors are used together with 90,000-kva transformers. The lines south of Milwaukee are 4/0 copper conductors. The remaining lines are 3/0 and 4/0 ACSR.

## Standard Towers

The square base double circuit tower is used for all lines on right-of-way not occupied jointly with railway, or on railway rights-of-way of sufficient width to allow space for their installation. These towers as well as the various types of bridge towers are designed to support 300,000-cir mil copper conductors strung so that the tension under heavy loading conditions will be 40 per cent of the ultimate. Under the same conditions, the tension in the $^3/_8$-in. Copperweld ground wires will be 39 per cent of the ultimate.



**Figs. 1, 2, and 3. Standard square base towers. Fig. 1 (left) is a suspension tower, Fig. 2 (middle) an angle tower, and Fig. 3 (right) a transposition tower**

The conductor spacing on the suspension tower is 13 ft vertical, with 26 ft and 32 ft horizontal separation, the middle arm being the longest in order to provide a horizontal offset of 3 ft between the conductors of a circuit. The vertical separation on transposition and angle towers has been increased to 16 ft in order to avoid reduction of clearances to ground below those obtained on the suspension tower. On angle towers, the arms are offset an amount equal to the horizontal displacement of the conductor due to the transverse load, thus placing the conductors in an approximately symmetrical position with respect to the head of the tower.

The number of different types of towers used in any line is a question of economics. Four different designs (exclusive of transposition towers) are used at various angles up to a right angle turn. Conductors are supported in suspension up to angles not exceeding 45 deg. Towers at angles of 0 deg to 45 deg are divided into three designs; namely, a standard suspension tower for angles not exceeding 4 deg (Fig. 1); an angle tower for larger angles but not exceeding 20 deg (Fig. 2); and a third type for greater angles up to 45 deg. The range of angles covered by each type will depend upon the number and size of angles in the line in question; but it is believed that the foregoing classification will prove to be economical for average conditions. A fourth design is a dead-end tower, suitable for use at angles greater than 45 deg and not exceeding 90 deg.

Transpositions are made on one tower without a reduction in length of, or crossing of, wires in the adjacent spans. Transposition towers (Fig. 3) are built by installing transposition arms on the body of a 20-deg angle tower, which when used for this purpose will withstand the loads specified for transposition towers.

Since the suspension towers are designed to withstand the unbalanced longitudinal loads due to 2 broken conductors, it has not been necessary to place strain or semi-strain towers at intervals in the line.

## Towers on Railway Right-of-Way

The utilization of private rights-of-way for both railway and transmission has called for marked departure from the square base double-circuit type of tower. Three general types of towers have been designed to best fit the conditions under which they are used.

The 2-track tower (Fig. 4) is a standard double-circuit tower set on a bridge structure spanning the tracks. It has been used on a right-of-way entering the city from the north through a suburban and city district.

The vertical side tower (Fig. 5) is similar to a standard double-circuit tower except that the face toward the track is vertical. The conductors are thereby placed partially over the tracks, requiring less width of right-of-way outside the tracks than if a standard tower were used. At present only one tower has been erected. The other tower and connecting truss will be erected when additional circuits are needed. These towers have been used along the rapid transit line entering the city from the west, where the right-of-way was of sufficient width to accommodate them.

The 4-track tower (Fig. 6) has been used on the same line but closer to the city where real estate values preclude the purchase of more right-of-way than is essential for railway purposes. This design centers the conductors over the rails and as close to each other as is practicable. Each set of conductors in an approximately vertical plane comprises one circuit so that they can be worked on while the others are operating. Access to the middle circuit is obtained by walking on a grating placed on the bottom of each truss. The truss is 5 ft in height. A modification of the 4-track tower is shown in Fig. 7. It was used where the railway grade was high and not of sufficient width to accommodate 4 tracks, at a point where the tracks cross the Menominee River.

All towers over tracks have been designed to accommodate railway trolley and feeders, and 26.4-kv lines in addition to the 132-kv lines.

Of the different types of towers utilized in extending the 132-kv system on or along private railway rights-of-way, it is obvious that the structures bridging the tracks cost more than the vertical side towers. The type of towers to be installed is a question of economics based upon real estate values at the particular location. In many of the outlying suburban areas there was the alternative of using the 2-track bridge type tower and utilizing, for the most part, the same right-of-way; or of purchasing additional right-of-way to permit the use of standard towers. The results of a study of this situation showed that the bridge tower is more economical if the cost of additional right-of-way for transmission only exceeds $1,200 per acre. If the cost is less than this amount, it is economical to purchase additional land adjacent to the existing railway right-of-way in order to accommodate standard towers.

## TOWER DESIGN

The design of the standard towers is for the most part along conventional lines, differing only in some details. One such departure from the usual practise is the use of the "drip plate," a 16-in. octagonal steel plate placed above the point of insulator support. Operating experience shows that under certain favorable conditions, water which collects on the crossarm brace will flow down the brace to the end of the crossarm and drip over the insulators, forming icicles. These icicles shunt the porcelain and have sufficient conductivity to permit a flow of current which will operate the ground relays. The function of the drip plate is to act as an umbrella in diverting the drip water away from the insulators.

The system is within the area defined by both the state and the national codes as a heavy loading district. Records show that wind has not exceeded 40 miles per hr (4 lb per sq ft pressure) while there was ice on wires, and the ice formation has not been as heavy as 1/2 in. ice radial thickness. However, it is known that in other parts of the state, ice has formed more than one inch in thickness. In order to guard against service interruption, a load equal to that imposed by one inch ice and 8-lb wind pressure at 0 deg fahr has been specified. This is approximately double the loading specified by the codes. All towers are designed to withstand transverse and vertical loads resulting from these conditions plus the unbalanced load due to any 2 conductors being broken. The unit stresses in the material are such that the elastic limit will not be exceeded if the loads specified are increased 10 per cent on standard towers and 25 per cent on towers spanning tracks.

The steel grillage type of anchor requiring no concrete, has been generally used for suspension and the lighter angle towers, while concrete has been used for the heavier towers and all towers over tracks. The Malone anchor has been utilized to some extent for suspension towers and found satisfactory where the soil conditions are suitable for its use.

The normal span length of the lines over 4 tracks is 510 ft. This is limited by the length of the maximum railway catenary span, which, on account of the track alinement, was found to be 255 ft. Other supports intermediate between the transmission towers carry the railway equipment only, resulting in a transmission span double that of the catenary span. The towers over 2 tracks are spaced at 600 ft. This also is double the railway catenary span, which on account of larger radii curves, is 300 ft. The double circuit square base towers are spaced at 650 ft maximum. This has been found to be an economical span length for the average conditions under which the various lines are constructed, taking into consideration width of right-of-way, land values, and clearances from other structures.

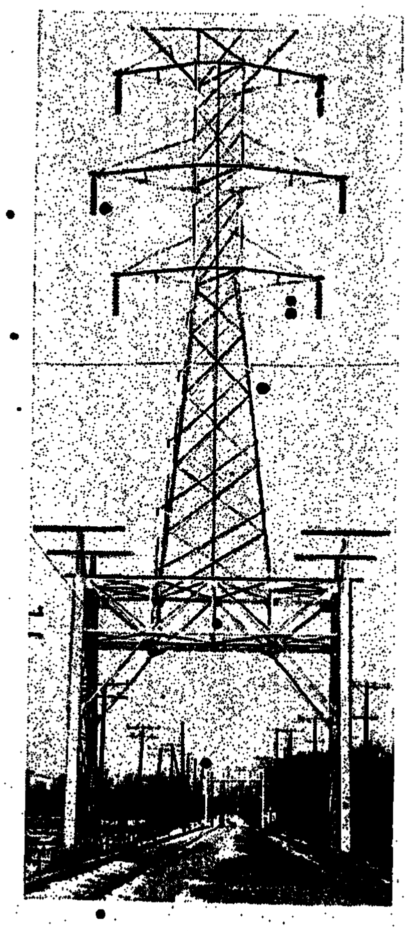


**Fig. 4. (Left) A typical 2-track bridge tower**

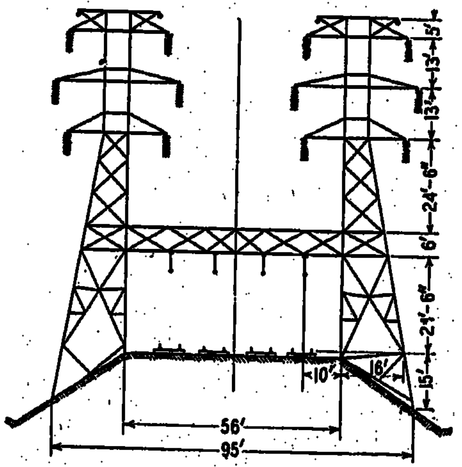

**Fig. 5. (Below) Elevation of a typical vertical side bridge tower with truss**

## GROUND WIRES

Lines constructed previous to 1925 were not equipped with ground wires, but provision was made for one wire at the tip of the tower approximately $8^1/_2$ ft above the top conductors. Operating experience available at that time on this and other utility systems, indicated that the presence of a ground wire did substantially reduce the number of interruptions due to lightning. Ground wires were then installed on all existing lines and since that time have been included in the initial construction of all lines.

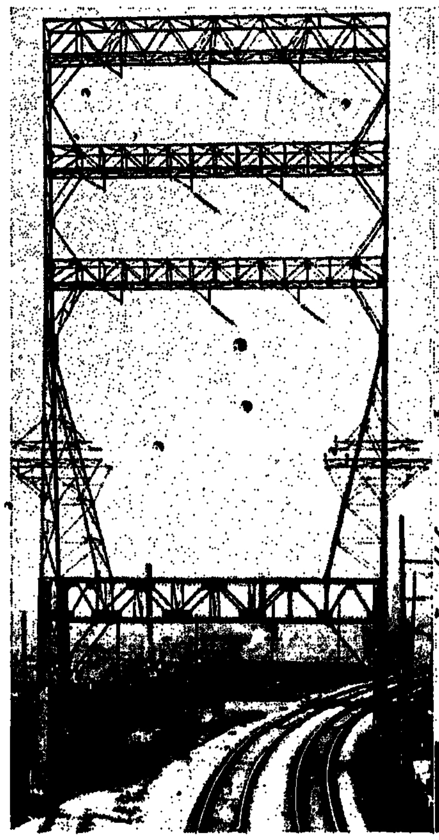

**Fig. 6. (Left) A 4-track, 3-circuit bridge tower**

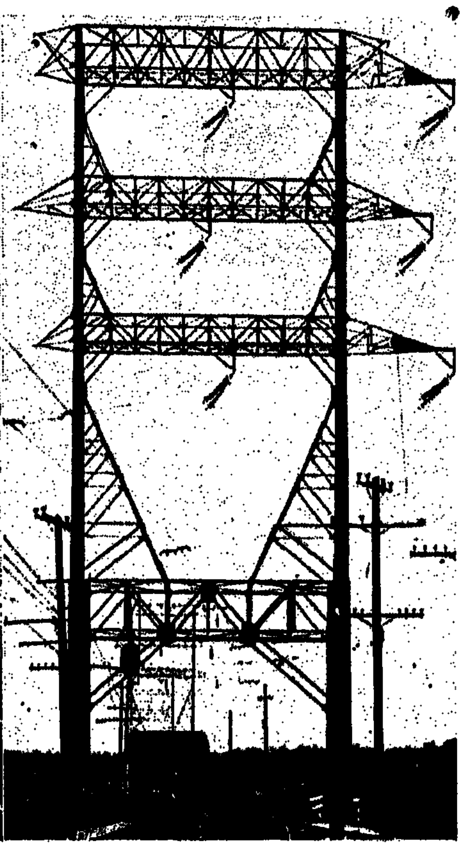

**Fig. 7. (Right) A 2-track, 3-circuit bridge tower**

Ground wires are $^3/_8$-in. Copperweld supported by a suspension clamp on suspension towers and by dead-end clamps at angles and dead-ends. The suspension clamp provides a flexible support, minimizing, if not eliminating, the bending of the wire at its support. This method of support is used as an added precaution against mechanical failure of the ground wire.

The line placed in operation early in 1931 is equipped with 2 ground wires, each of which is offset 3 ft horizontally and separated 12 ft vertically from the top conductor. The sag of the ground wire is less than that of the conductor, making an average vertical separation of approximately 16 ft.

## INSULATION AND PROTECTIVE DEVICES

The older 132-kv lines are equipped with 10 $4^3/_4$-in. spaced suspension insulator units with 15-in. horns at the conductor end. The horns are effective in protecting the conductor against burning, and the lower insulators against damage by power arcs. This insulator string has an impact flashover of approximately 700 kv. Flashovers and the power arc following have often damaged the porcelain of the upper insulators of the string, but there has been only one case, and that during a severe rain storm, when service could not be restored without replacing insulators.

Flux controls, devices having the general appearance of horns, but having insulators on the tips, are used on 32 miles of line. Laboratory tests show that these devices will protect the insulators against discharges of from 50,000 to 70,000 cycles per sec. Although it has been shown that such frequencies can be present on the line, it has not been shown that they occur frequently enough to warrant protecting against them. This is borne out by the operating record of this line, which, from the time of the installation of the flux controls in 1926 to date, is substantially the same as the other circuit carried on the same towers, but equipped with 15-in. horns.

The most recent line to be placed in operation is equipped with V.S. arcing horns on a suspension insulator string consisting of 10 $5^3/_4$-in. units. The impact flashover of this assembly is 820 kv The purpose of the horns is to protect the porcelain against damage by confining the arc to the horn tips, thus permitting restoration of service immediately following the oil circuit breaker operation. Dead-end insulation consists of 2 12-unit strings in parallel and equipped with V.S. horns on which the impact flashover is 980 kv.

At the Lakeside generating station, near Milwaukee, each outgoing 132-kv line is fed through its own transformer bank, which is protected by a lightning arrester against surges originating on the line. At substations the transformers are protected by a lightning arrester connected to the bus. Ultimate plans provide for an arrester on each bus section to which transformers are connected.

At all generating stations and substations connected to lines equipped with V.S. horns, the horn-gaps nearest the station are set to protect the station apparatus as well as the line. At switching stations where there is no equipment with bushings connected to the 132-kv line, no reduction need be made in the length of gap used on the suspension tower. Laboratory tests show that this gap of approximately 47 in. will always flash over before the bus insulators or the 4-unit pillar insulator on the air-break switches. At stations where there are bushings to be protected, the gap has been reduced to $36^1/_2$ in., resulting in a flashover value just below that of the bushings. These protective horn-gaps are placed on the dead-end line insulators, except where they would be in close proximity to an air-break switch. In this case they are placed on the tower one span away.

The 66-kv system of the Wisconsin-Michigan Power Company in upper Michigan consists of both steel tower and wood pole construction. The steel towers are of the conventional double circuit type similar to those on the 132-kv system, except that neither the loads nor clearances are as great. Where a single circuit line of small conductors meets the requirements, the wood poles are the more economical. Another advantage over steel towers is that they can be set along highways and streets, where they are available for distribution circuits.

# Brass Tacks in Economics

**Less investment money and more buying money is needed today; one proposal to increase buying power without harming business is by the drastic taxation of great incomes. This is the thirteenth article in the Engineering Foundation's symposium "Has Man Benefited by Engineering Progress?"**

By
DAVID CUSHMAN COYLE Consulting engineer, New York, N. Y.

SCIENCE never is finished, but the engineer cannot wait. While research is exploring the theory of stresses, the engineer must take what facts he can get, use the means available, and drive the job forward. It is the same with economic fact-finding. Look at the bituminous coal industry: Facts are basic, but not dynamic. Making the economic machine run is a problem in simplification, decision, and determined action. What is wanted? Where is the sticking point? What power is available? What will it cost?

There are two incompatible economic projects. One is that of bringing the great accumulations of capital through the storm with the least possible loss. The other is involved in this question: If we can easily make all the things any reasonable person wants, and plenty for everybody, why not do it? Radicals and conservatives will favor the first project, the former because they know it leads to revolution, the latter because they do not know that the attempt is hopeless. The second project is a constructive, common-sense idea, and therefore peculiarly suited to the engineering mind. Following is an outline of this second project.

## TOO MUCH INVESTMENT MONEY POISONS BUSINESS

The sticking point is in the construction and machinery industries, the production of "capital goods." Too much money goes into factories and office buildings and new coal mines; then overhead consumes all the profits, and paralysis sets in. The system as a whole is as inefficient as possible. First we build factories that cannot run and floor space that nobody will occupy; then we spend several years doing nothing of any consequence. Our work is stultified by the irrational behavior of finance.

Investment money flows into industry and trade when prospects look good, and causes overexpansion; then it flows out and causes deflation. It causes instability and profits thereby, and for that reason it is poisonous to business. The Federal Reserve is supposed to counteract this action of private finance; but it has not been strong enough. Investment money flows into overequipment, and when industry has been well poisoned it vanishes in bankruptcies, wrecking business, but not removing the excess equipment. There is too much investment money. The opportunity to invest money without poisoning business is limited. Moreover there is too little buying money. The income of the country must be directed more to useful consumption and less to economic poison.

What power is capable of turning the flow of money into useful channels and releasing us from the vicious circle of wasted work and unemployment? History indicates that those who suffer most are likely to be most interested in applying a remedy. Working drawings must be intelligible to workmen; any plan that is to come down out of Utopia and take on reality must sacrifice comprehensiveness to simplicity. The most obvious device is communism, but it hardly seems suited to the American temperament. A more practical method of steering money into consumption would be one that would be acceptable to the workers and the middle class, because together they have the necessary power to put it into action. Heavy taxes on the great individual incomes with rebates for approved contributions, would effectively reduce overbuilding and turn the money into public and semi-public construction; this would increase buying power without harming business.

## DRASTIC TAXATION OF GREAT INCOMES WILL STABILIZE BUSINESS

What will it cost to stabilize business growth by drastic taxation of great incomes? First, it will cost giving up forever the hope of becoming a multimillionaire. Success, beyond a certain point, will have to be measured in honors, fame, offices, anything else but vast sums of money. The money is needed to lubricate business via the buying market. Second, it will mean slowing the maximum rate of construction of new plant. Our present *average* rate is slow because we stop periodically. This could be avoided if we would tax consumption and use the money to tear down old plant; but although it would cure overequipment it would be inefficient because too much energy would go into premature replacement. There is a finite optimum rate of replacement, which with our tremendous productive power we could overpass easily. By diverting capital funds into the destruction of old plant as well as to building cultural equipment, we could get the maximum of useful products out of the system in the long run.

The third cost of the limitation of capital accumulation will be that it will tend to decentralize initiative. The incentive for centralized control will be reduced and that for setting up small concerns

---

This article has been checked by Virgil Jordan, economist, McGraw-Hill Publishing Company, Inc., New York, N. Y.

will be increased. That may seem horrifying at first; and yet, could any arrangement be more inefficient than the present one? In any event it is the price of freedom, and of the overall efficiency which we lack now.

No system with the high productive power of our own can be made to run unless the construction of equipment is artificially kept in check. If we go in for centralization, we shall be forced to adopt socialism as a means of limiting investment. If we limit the volume of investment money by taxation, we can avoid the abolition of individual initiative. The latter method crudely but effectively will do the job; it is simple enough to be comprehended by the voters who have the power to put it into action; and the cost is less than the cost of drifting on into collapse and revolution. It will be well for engineers to consider these points, devise a still simpler and more effective plan if possible, and then push for action.

---

# Welding Steel Structures

WELDING with gases and electricity are relatively new processes but have a background of more than a decade of scientific research. In recent years such welding has been adapted to buildings and bridges. Noise elimination, economies, and ease of application are a few reasons for adoption by the structural steel industry.

Welding came to the attention of engineers during the World War as an aid in shipbuilding. Prior to this time, it had been used with varied success in repair work, particularly on the railroads. Good welds could be produced under certain conditions, whereas poor welds resulted under others. Welding experts were unable to give satisfactory reasons for this, but investigations started during the war were continued. With the organization of the American Welding Society and its research department, the American Bureau of Welding, this research work was expanded.

Leading structural engineers a few years ago began to study the application of welding to the fabrication of steel structures. Investigators in this country and in Australia undertook tests. A few important structures were fabricated by welding, including some gas holders in Australia, some small ships here and in Europe, and a few small buildings in this country and in England.

An outstanding contribution to the extension of welding in structural work was the 5-yr program of the Structural Steel Welding Committee. Its scope and thoroughness commanded the attention of architects and engineers. It involved the fabrication and testing of several thousand specimens welded by 61 welders at 39 shops and tested at 24 laboratories including college and commercial institutions, and the U.S. Bureau of Standards. This research disclosed no harmful effect on the base metal due to welding.

Since tests on 2,495 specimens indicated that joints commercially welded by qualified welders may be expected to possess strengths within 12 per cent of general average results, engineers and architects may feel secure in expecting in their completed structures, the strengths required.

A few random instances will bring out these advantages. A new hotel building had to be erected at Hot Springs, Va., between 2 existing structures. It was necessary to avoid the noise of riveting. This structure was 12 stories high, and was the first so-called tier building of this size to be welded. A 5-story heavy duty warehouse was constructed by American Bridge Company for Westinghouse Electric & Manufacturing Company. The continuity of beams and girders which was provided resulted in a 12 per cent saving in steel.

A 10-story office building in Cleveland, housing physicians and dentists, was enlarged without disturbing the occupants. The gas torch and the electric arc made this possible, thus saving the owners thousands of dollars in rentals. It was necessary to make only small openings in the old walls uncovering the face of the old steel where the connections were to be made. Much wrecking was eliminated.

Steel building frames may be welded with either the gas torch or the arc. The largest structure thus far welded with a gas torch is a research laboratory 75 ft wide, 260 ft long and $42^1/_2$ ft high, at Niagara Falls. The tallest arc welded structure is a 19-story office building for the Dallas (Tex.) Light and Power Company. The heaviest welded truss to date weighs 60 tons; it has a span of 96 ft and a height of 18 ft. In the United States several hundred steel structures have been welded either totally or partially. No failure has occurred in any welded joint.

Aside from the economic value of noise elimination, in many locations, the saving lies principally in the use of less steel in trusses or plate girders. In the multi-story building frames consisting of welded beams and columns, the decrease in weight of steel is small unless the beams be made continuous; but thus far the cost of additional welding has offset the saving in steel. In several buildings, some of them 14 stories in height, the cost to the owners when the shop work was riveted and field work welded, was the same as if both shop and field connections had been riveted. This equality reveals a decided advance in a short time. In ordinary roof trusses savings in weight of steel are pos-

---

From *Research Narratives*, April 15, 1932, published by the Engineering Foundation, 29 West 39th St., New York, N. Y. Based upon information contributed by W. Spraragen, Secy., American Bureau of Welding, New York, N. Y.

sible amounting to as much as 36 per cent. Similar savings are obtained in plate girder construction.

The American Institute of Steel Construction is sponsoring the battledeck floor for buildings. It consists of thin flat steel plates two feet or more wide resting upon the upper flanges of parallel I-beams. As the adjacent edges of two plates run along each I-beam and a narrow space is left between them, these edges are welded together and at the same time to the top of the I-beam, thus producing a composite beam. Automatic machines are available for the welding.

More than 125 municipalities have adopted welding in their building codes. With accurate design data, control of products is made sure through the employment of qualified welders and inspectors, and designs adapted to welding.

Welding has been helpful in steel buildings to resist earthquake and wind, which in some instances would require unusually elaborate designs if riveted. An example is the new headquarters of the Southern California Edison Company, Ltd., in Los Angeles.

All-welded steel frame houses are possibilities of the future. Several such experimental houses have been erected at a cost which compares favorably with wooden structures. General adoption would provide an outlet for more than a million tons of steel annually.

# Electrochemistry and Hoover Dam

**Two mining authorities here outline some of the possibilities for electrochemical developments at or near Hoover Dam in connection with the expected availability of large quantities of cheap power and water and the known mineral deposits of the West.*—Editors.**

WITHIN 6 years the construction of Hoover Dam and the power plants probably will have reached the operating stage and this vast new source of power then will be available for industry.

The average annual flow of the Colorado River is calculated at approximately 24,000 cfs, and if this average flow can be maintained the year round at the full head provided by the 580-ft dam about 1,000,000 hp will be generated. Government engineers, taking into consideration the probable range in flow and head, have set the figure for power contracts at 660,000 firm horsepower, which can be assured at all times of the year. During the months of heavy run off the power plants should be able to generate their full 1,000,000 hp; hence there will be 340,000 excess or secondary horsepower. The cost of firm power at the switchboard will be close to 2.15 mills per kwhr, equal to $14.05 per hp-yr, and the cost of the secondary or off peak power will be close to 0.8 mill per kwhr, or $5.22 per hp-yr. At no place in the country can such cheap power be obtained today.

The electrochemical industry is in a state of flux because the cost of power from its old sources has increased so much (to $30 per hp-yr at Niagara) that the industries have gone to Canada and Norway and built new plants. Dr. C. G. Fink, secretary of the American Electrochemical Society and an accepted authority on matters concerning the electrochemical industry, made the following statement at the hearing on disposal of Boulder Dam power before Secretary Wilbur in Washington, D. C., in November 1929: "It is my opinion and conviction that the American electrochemical industry will be ready to absorb all of the power developed by the Boulder Canyon project as soon as it is available." Doctor Fink also stated that "transmission costs are higher than transportation costs for raw material or finished product."

The power situation as briefly outlined, coupled with the fact that the Hoover Dam area is one of the richest in the world in raw materials used by the electrochemical industry, insures the creation of an immense electrochemical and electrometallurgical industrial center in southern Nevada. The following is a brief résumé of the more important industries that will be created to use this cheap power, and a brief description of the metallic and non-metallic resources in southern Nevada and contiguous territory.

## ELECTRIC FURNACE INDUSTRIES

Numerous electric furnace industries are possible. Calcium carbide can be manufactured, for limestone of high purity exists in unlimited quantity near the dam. Although coke will have to be brought in from Utah, the low power rate at the dam will more than offset this.

Cheap power may make possible the calcination of this pure limestone in electric furnaces, obtaining quicklime as one product, carbon dioxide gas as another. Dolomite also occurs in unlimited beds near at hand, to be calcined for various uses, as done there now with oil furnaces. The carbon dioxide gas would fit into the picture to convert synthetic ammonia to carbonate, which in turn may be elutriated with ground gypsum to form ammonium sulfate fertilizer, and produce hydrated lime as a by-product. By this process millions of tons of ammonium sulfate are manufactured annually in Germany.

Ferro-alloys of vanadium, molybdenum, manganese and silicon can be manufactured from ore supplies all within 40 miles of the dam. Tungsten will come from central Nevada. Pig iron can be brought from Utah, or iron for such alloys can be produced from the large deposits in southern California and Nevada. In San Bernardino County, California, is a splendid deposit of at least 5,000,000 tons of magnetite, only 150 miles by rail from the dam site. In northeastern Riverside County, California, is the great Iron Chief deposit, conservatively estimated at from 20 to 75 million tons, distant only 200 miles from the dam. Other large deposits also exist in the West.

---

* Abstracted from an article "Possibility of Electrochemical Industries at Hoover Dam" written by Jay A. Carpenter—professor of mining, University of Nevada—and Alfred Merritt Smith—mining engineer, Nevada State Bureau of Mines—and published by the American Institute of Mining and Metallurgical Engineers, Inc., in "Mining and Metallurgy" for August 1932.

The sponge-iron process has possibilities wherein Utah would be called on to supply cheap slack coal for the necessary reduction before the electric smelting of the sponge iron. The pioneer plant at Heroult, Calif., several years ago proved electric iron smelting to be practicable, and success dependent on costs alone. Here is a wide new field in the direct production of steel and steel alloys from the ore.

## NITRATES AND AMMONIA

Very cheap power and an absence of coal suggests the adoption of some method of nitrogen fixation using only air, water, and power, such as the Birkeland and Eyde and Doctor Schonherr's methods in use in Norway by plants consuming 360,000 hp. The nitric acid so produced has high market value, and nitrate nitrogen is desirable for explosives manufacture, a large industry on the Pacific Coast. High-power explosives for military protection can be manufactured near the dam, a point remote from air attack and near the great new United States munitions storage depot at Hawthorne, Nev.

Although the Haber-Bosch ammonia process now is used to produce most of the world's synthetic ammonia, nearly all of the plants consume coke and coal both for power and to produce the gases used. However, in the last few years synthetic ammonia made from hydrogen derived from the electrolysis of water and nitrogen obtained from the air, has become of importance where cheap power is available.

Tadanac, near Trail, B. C., offers an outstanding example of water electrolysis on a commercial scale. Hydrogen from the electrolytic disassociation of water, and nitrogen from a liquid air unit are used in producing synthetic ammonia by direct combination under pressure with a catalyst. This, too, although the plant is not remote from good sources of Washington coke and coal. Tadanac long has been a great center for electrolytic lead refining, and it was there that selective flotation of complex lead-zinc ores made a great advance. The $10,000,000 fertilizer plant now under construction there consists of an electrolytic hydrogen unit to produce 3,000,000 cu ft of hydrogen per day; a liquid-air unit for the production of nitrogen; and a synthetic ammonia unit to produce 47 tons of anhydrous ammonia per day. Thus have low-priced power and basic materials built up this great group of industries in a location more remote from markets and having a climate much inferior to that of the Hoover Dam for living, labor, and operating conditions.

## ELECTROLYSIS

Electrolysis of salt produces sodium hydrate and chlorine, the base and acid for a wide range of chemical uses. Four large salt deposits in Virgin Valley, 50 miles from Hoover Dam, contain at least 25,000,000 tons of rock salt. Rock salt and also calcium chloride occur in inexhaustible quantities at Bristol Dry Lake, San Bernardino County, 150 miles from Hoover Dam. Great quantities of sodium hydrate might find use in the refining of California petroleum. Hydrochloric acid made from the chlorine may possibly be used in the manufacture of pure iron by electrolysis of a solution of ore in acid. Cheap power would be the key to this method, with the natural resources ready at hand.

## THE METALS

*Zinc.* The U.S. Bureau of Mines reports that Arizona, Nevada, New Mexico, Oregon, Washington, and Utah mines produced 93,018 tons of recoverable zinc in 1930. For the same year Colorado and Montana produced 155,718 tons. Most of the ore was reduced in electrolytic plants in Montana and Idaho and represents 26.5 per cent of the total United States production. During the years 1930 to 1932 the mines of Pioche, Nevada, enormously increased their ore reserves; they now have about 4,000,000 tons of ore blocked out, with the possibility of much more lead-zinc-manganese ore to be developed soon. To provide for this increased production, particularly in Nevada, large concentrating and calcining plants may be built at Pioche, about 150 miles north of the dam. The calcine could be shipped to the dam for electrolytic refining. About 16 per cent of all the sulfuric acid used in the United States is produced by zinc-roasting plants. Probably all of the Pioche acid would be absorbed by industries at the dam, chief of which should be the refining of blister copper.

*Copper.* In the West, there are electrolytic copper refineries at Great Falls, Mont.; Tacoma, Wash.; and a new plant at El Paso, Tex. Doctor Fink states that these will not take care of western copper output, but will leave all of Nevada (54,601 tons in 1930) and half of Utah and Arizona (about 500,000 tons in all) to be sent east for refining. It would appear that for more economical operation a plant should be located at Hoover Dam, in the center of the heaviest producing districts, and a point on the direct route to the Coast.

*Aluminum.* Doctor Fink points out that all aluminum used in the western half of the United States is subject to an expensive cross-haul, bauxite from Arkansas going east for reduction and then west again as metal. Six million pounds per year is shipped to the Orient, in addition to large amounts used in the western states. A deposit of pure alunite is being developed at Sulphur, Humboldt County, Nev. Marysvale, Utah, also is a source of this aluminum-potash mineral. Other localities in Nevada and Utah may be able to supply some of this ore. A commercial process for recovering both aluminum and potash from alunite should not be difficult to work out, given cheap power and abundant water.

*Manganese.* Various deposits of manganese ore occur in the western states. In Nevada, at Golconda and Ely, small tonnages of high-grade ore are produced, and at both Las Vegas and Pioche are large bedded deposits. The probable tonnage of manganese ore, associated with zinc and lead in the Pioche district, now amounts to about 4,000,000 tons. Possibly 2 or 3 times as much will eventually be developed. The Combined Metals Company at Pioche is perfecting a commercial process for the separation of manganese, which can probably be carried out most advantageously at the dam site, where, in any event, the next steps of making ferromanganese or using the ore in chemical industries would be carried out. Only 10 miles northwest of the Hoover Dam is another large bedded deposit of manganese ore, which geologists Hewett and Webber of the U.S. Geological Survey estimate to contain at least 500,000 and possibly 1,000,000 tons. As manganese ore imports in 1930 were 585,568 long tons, and domestic production of all classes, including 708,000 tons of manganiferous iron ore was only 845,000 tons, the need of cheap domestic manganese is seen. Ferromanganese can be made cheaply in electric furnaces at the dam site, and thus be ready for market at exceedingly low cost for the ores.

*Tungsten.* Nevada and California together produce most of the tungsten consumed in the United States. The largest western production is made at Mill City, Nev., and Atolia, Calif., which together produce about 80 per cent of all that used in the United States. (In 1930, 702 tons of 70 per cent $WO_3$ was produced.) A portion of Nevada's production of 64 per cent of the total, which is now shipped to Niagara Falls for reduction, could be converted to ferro-tungsten at the dam, for western and Oriental consumption, at a great saving.

*Other Minerals and Metals.* Within commercially practical distances of Hoover Dam lie tremendous deposits of other minerals and metals including alum, borax, brucite, gypsum, clays (bentonite, kaolin, diatomite), feldspar, fluorspar, limestone, magnesite, molybdenum, silica (good quality), sodium sulfate, sulfur, and vanadium.

### ECONOMIES POSSIBLE

To the materials already mentioned must be added platinum, gold, silver, mercury, cobalt, and bismuth, all of which are found in Nevada and California near the Hoover Dam site. Great economies to the mining industry seem possible through the establishment of reduction plants and refineries at this source of electric energy.

# Distribution System Lightning Protection; Operating Experiences With Lightning Arresters

**Operating experience demonstrates that lightning arresters provide sufficient protection to justify their installation on electric power distribution systems even where low arrester ground resistance cannot be obtained. Limited experience with the interconnected lightning arrester ground and grounded secondary neutral confirms the results of laboratory and field tests covered in a group of articles published on p. 633–47 of the September issue of ELECTRICAL ENGINEERING.**

PROTECTION of electric power distribution systems from disturbances due to lightning is a problem of major importance, since many interruptions to customers are due directly to troubles from that source. Statistical studies show that lightning arresters provide sufficient protection on distribution systems to justify their installation economically. Results of 3 such studies on 3 typical large power systems are covered in the 3 articles immediately following this introduction.

The first article, by Roper, treats of a cooperative investigation on the system of the Commonwealth Edison Company, Chicago, conducted by several lightning arrester manufacturers in cooperation with the power company. The second, by Haines and Corney, gives the results of a study on the system of the Edison Electric Illuminating Company, Boston, in a region where high ground resistances prevail. The third article, by Dambly, Ekvall, and Phelps, covers a study on the different types of lines that make up the distribution system of the Philadelphia Electric Company, and includes field tests with the interconnected primary arrester ground and grounded secondary neutral.

From the results of these and similar studies, quite definite rules now can be laid down for reducing the effects of lightning disturbances on distribution circuits. As determined in previous investigations, a marked improvement in protection is effected by increasing the arrester density, that is, the number installed per square mile of area protected. The age and size of transformers also appear to have some effect, the smaller transformers being more susceptible to lightning troubles as are those of older design. Low resistance for arrester grounds appears to be of great importance, although considerable protection can be obtained even with ground resistances as high as 1,000 ohms. There is a difference of opinion as to whether grounded systems are less susceptible to lightning disturbances than are ungrounded systems. A difference of opinion also exists in regard to the shielding effect of tall buildings, trees, and other structures.

# I—Experience on a Typical Urban System

By
**D. W. ROPER**
FELLOW A.I.E.E.

Commonwealth Edison Company, Chicago, Ill.

By taking advantage of knowledge gained from a 20-yr statistical research investigation of lightning protection for distribution circuits (Fig. 1), it appears possible to reduce the number of transformer troubles caused by lightning in Chicago to less than one case of trouble per year per thousand transformers in service. This article presents some of the later results of that 20-yr study.

Following the development of the cathode ray oscillograph in form suitable for tests on lightning arresters, it was noted that test results, as then made and interpreted, placed the several types of arresters in a different order of merit from the order indicated by field investigations. This resulted in a conference with the lightning arrester manufacturers on the subject in January 1927, at which time plans were formulated for determining the causes of these discrepancies. Practically all of the additional information on the subject recorded in this article has resulted from the intensive study begun during this conference. During the succeeding years 6 more conferences were held; as a result, practically all of the differences which appeared in the first conference have been reconciled. As the manufacturers of lightning arresters now are able to make tests with the lightning generator and to interpret the results by means of the cathode ray oscillograph, so that by such studies the relative merits of various types of arresters can be closely determined, the detailed statistical investigations in Chicago no longer are warranted and hence have been practically discontinued.

## Chicago Distribution System

The system of distribution in Chicago is a 4-wire 3-phase 2,300/4,000-volt system with the neutral grounded at the substations. All of the 606 circuits leave the substations underground; the feeders and about $^1/_5$ of the mains are underground. On August 1, 1931, there were 33,093 transformers connected to the overhead mains; in addition 1,593 were installed in manholes or vaults and connected directly to underground primary mains. Over 800,000 customers are served by this distribution system, which covers about 120 of the 210 square miles within the Chicago city limits.

All line transformers are single-phase, with 2,080-volt primaries and 115/230-volt secondaries. Lighting transformers are connected between a phase wire and neutral; the secondary neutral wire is well grounded along the secondary mains and on the customers' premises. Transformer cases are not grounded. Large power installations consist of 3 transformers connected in $Y$ on the primary and in $\Delta$ on the secondary; the common point of the primary connections is not connected to the primary neutral, and the middle point of one transformer secondary is grounded. Smaller power installations consist of 2 transformers each connected between one phase wire and primary neutral with the secondaries connected in open $\Delta$. Secondary lighting mains generally are only one block long, but about $^4/_5$ of these secondary mains have their neutrals connected with the neutrals of mains in adjacent blocks.

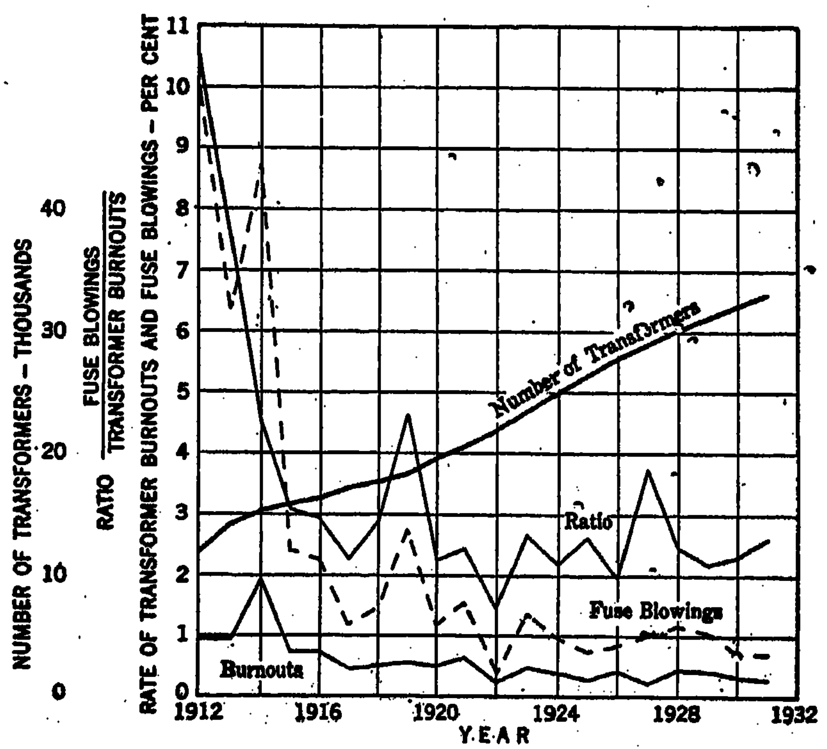

**Fig. 1: Records of transformers and lightning troubles for a 20-yr period**

Even though the number of transformers doubled between 1915 and 1931, the actual number of transformer burnouts and fuse blowings remained fairly constant at 105 and 275 per year, respectively

One 3-kv and one 300-volt arrester (Fig. 2) are installed on the same pole with each lighting transformer; similar installations are made at the banks of 2 or 3 power transformers with the further limitation that the maximum number of phase arresters on

---

Based upon "Studies in Lightning Protection on 4,000-Volt Circuits—III" (No. 32-19) presented at the A.I.E.E. winter convention, New York, N. Y., Jan. 25–29, 1932.

### Table I—Results of Examination of Transformers Burned Out in Chicago by Lightning During 1927–30, Inclusive

| Apparent Lightning Entrance | No Transformers Examined | Per Cent |
|---|---|---|
| Primary only: | | |
| Phase wire | 133 | 28.0 |
| Neutral wire | 32 | 6.8 |
| Phase and neutral wire | 42 | 8.9 |
| Total, Primary only | 207 | 43.7 |
| Secondary only | 100 | 21.1 |
| Secondary and primary | 105 | 22.2 |
| Doubtful | 38 | 8.0 |
| Indeterminate | 24 | 5.0 |
| Total | 474 | 100.0 |

Note: In these investigations a transformer is considered to be burned out when it cannot be restored to service without removing it from the pole. About 40 per cent of the transformers were repaired without replacing the coils.

transformers in any one block is 3. Similar installations are made on all cable poles. No lightning arresters or similar devices are installed in any of the substations, on the secondary mains for light or power, or on transformers connected to underground mains.

At present 15 types of 3-kv arresters are in use on the system, which, for the purpose of this investigation, was divided into 162 areas with only one type of arrester in any area. The several areas for each type are scattered throughout the city. For grounding the arresters 10-ft ground rods are used except in sandy regions, where 15-ft rods are used; in the few rock areas special methods are employed.

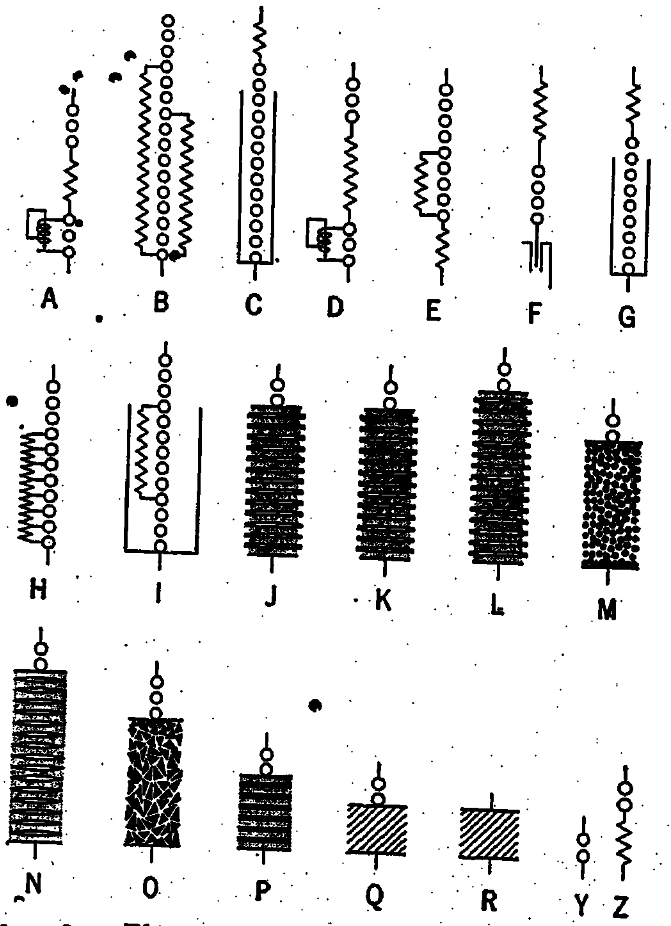

**Fig. 2. Electrical diagrams of arresters used**

Gaps and resistors are shown by conventional symbols, lower end of diagram is ground side. Types A to R are 3-kv arresters. Types Y and Z are 300-volt arresters. In types C and G narrow grounded bands of metal are carried up the sides, while in type I, a grounded metallic cylinder surrounds the lower $^3/_4$ of the arrester. Arresters J to R are valve types. Arresters are arranged in the order in which they were installed on the system

## EXAMINATION OF BURNED OUT TRANSFORMERS

Records of the examination of 474 transformers burned out by lightning (Table I) indicate that burnouts starting in the secondary winding (Fig. 3) were nearly half as numerous as those starting on the primary. Lightning potentials on the secondary service wires, however, have caused but little trouble on customers' premises. Information obtained in the examination of the transformers confirms the suggestion in the 1914 paper of the author that careful attention should be given to clearances of leads inside and outside the transformer case. (See "Experiences With Line Transformers," A.I.E.E. TRANS., v. 33, 1914, p. 685.)

Evidences of direct strokes, as indicated by shattering of poles or cross-arms, were found on only about 15 poles per yr., or one in 9,000. Only about 5 per cent of the transformer failures appear to be caused by direct strokes. Apparently there are practically no traveling waves on the distribution system. This assumption is based upon the fact that records for transformers at the open ends of primary wires show that the percentage of trouble is about 20 per cent below the rate for other transformers. Were traveling waves existent on the system, there would be an increased percentage of trouble due to piling up of potential at these points.

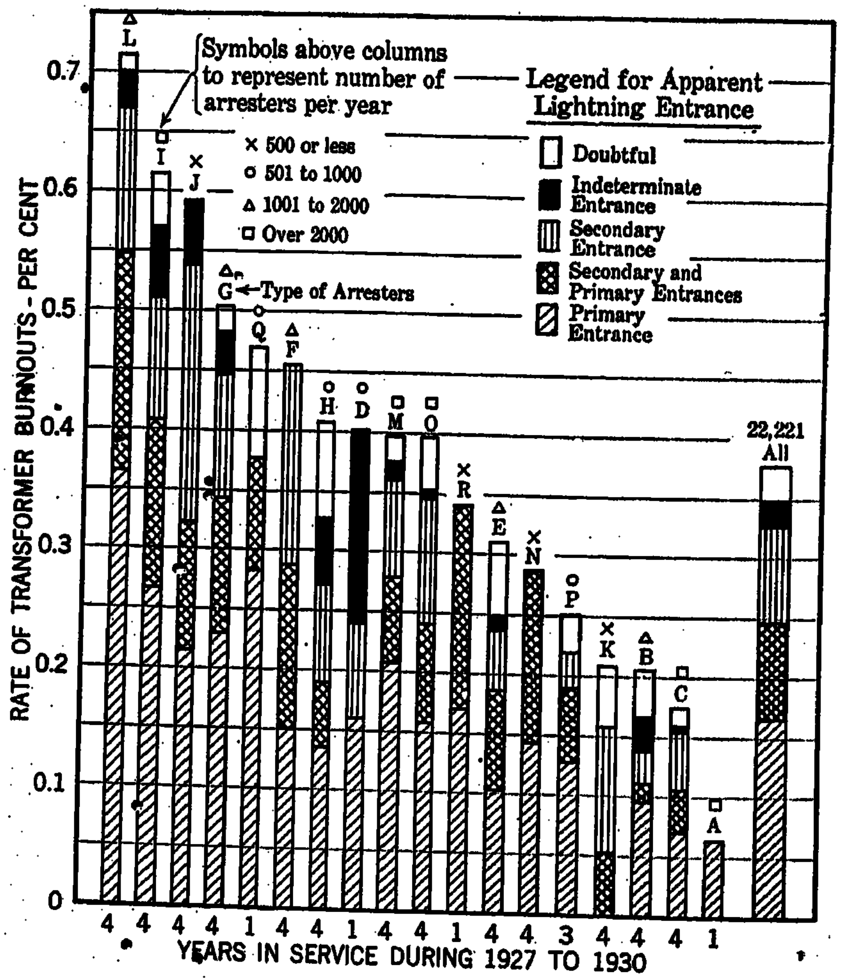

**Fig. 3. Performance of different types of arresters**

Averages are not corrected for size, age, or density of transformers. Probable errors in the individual cases are from 10 to 25 per cent, except for type A, for which only one year's performance is shown

## EFFECTS OF VARIOUS FACTORS

From the results of the investigation certain factors have been found to affect lightning troubles on the distribution system as follows:

### 1. Underground primary mains.

The 1,593 transformers installed in manholes or vaults and connected to underground primary mains had a rate of burnout due to lightning of only $^{1}/_{80}$ of 1 per cent per annum in the past 5 years.

### 2. Grounding of primary neutral.

One advantage of a 4-wire 3-phase system with neutral grounded in the substation is that it permits the installation of 300-volt arresters on the neutral wire of the overhead primary mains and 3-kv arresters on the phase wires, whereas with the neutral ungrounded arresters rated at 3 kv and 6 kv, respectively, are required. During a lightning discharge the 300-volt arresters break down quickly, after which the primary neutral wire acts as a ground wire to reduce the maximum voltage which otherwise would be reached by the primary phase wires. This, together with the use of phase arresters of lower voltage rating gives the grounded neutral system an advantage over systems with ungrounded neutral by a reduction of about 40 per cent in the maximum crest voltage to which the transformers are exposed to induced discharges. This advantage also is indicated by the fact that, although no arresters are installed in substations, flashovers due to lightning in the substations in Chicago are entirely unknown and burnouts of voltage regulators due to lightning in recent years have averaged about $^{1}/_{20}$ of 1 per cent per annum. In addition, the number of cable failures due to lightning has been only about 2 per year though there are 3,800 points of connection to the overhead mains.

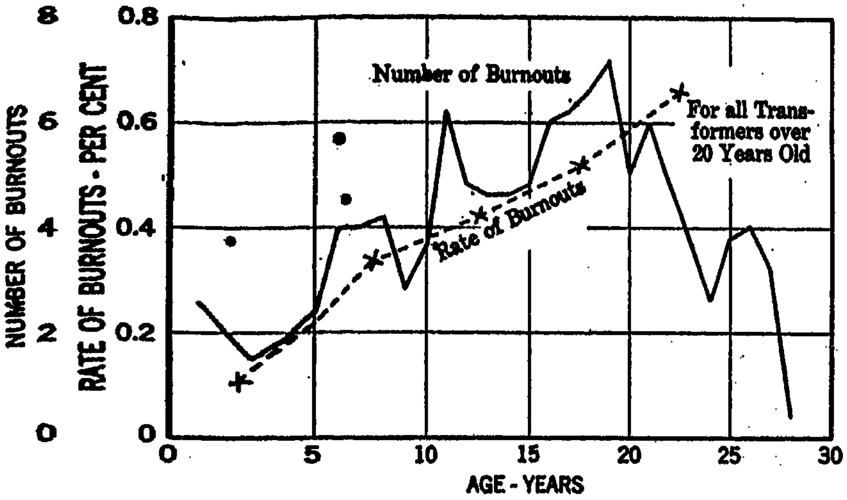

**Fig. 4. Relation between age of transformers and burn-outs due to lightning**

Figures shown are averages for 1927–31

### 3. Density of arresters.

This subject, a most important one, was covered quite thoroughly in the author's 1920 paper "Studies in Lightning protection on 4,000-Volt Circuits—II" (A.I.E.E. TRANS., v. 39, part 2, p. 1395). The conclusion reached in that paper was that "There is a very marked improvement in the effect of lightning arrester protection with an increase in density. . . . "

### 4. Size of transformers.

Recent records confirm statements in preceding papers that lightning troubles decrease with increasing transformer size. In Chicago some reduction of troubles has been effected by discontinuing purchases of transformers of capacities lower than 5 kva.

### 5. Age of transformers.

The rate of burnouts has been found to increase several fold with age of a transformer (see Fig. 4).

### 6. Resistance of arrester grounds.

Records indicate that apparently any extra expense to reduce the resistance of lightning arrester grounds below 50 ohms is not warranted.

### 7. Shielding effect of trees and buildings.

As near as could be determined, the shielding effect of trees, buildings, and other tall objects against induced discharges is practically zero for Chicago conditions. There is no way of determining even approximately the extent to which trees and structures shield the lines against direct strokes.

### 8. Extent and intensity of lightning.

Although each type of arrester was installed in several areas widely scattered over the city, the intensity of lightning in these areas varied from year to year; consequently annual variations in protective characteristics of the arresters were observed, as indicated in Fig. 5. This also indicates that to obtain reliable data from such investigations, a great many arresters must be used and the field trial must extend over several years.

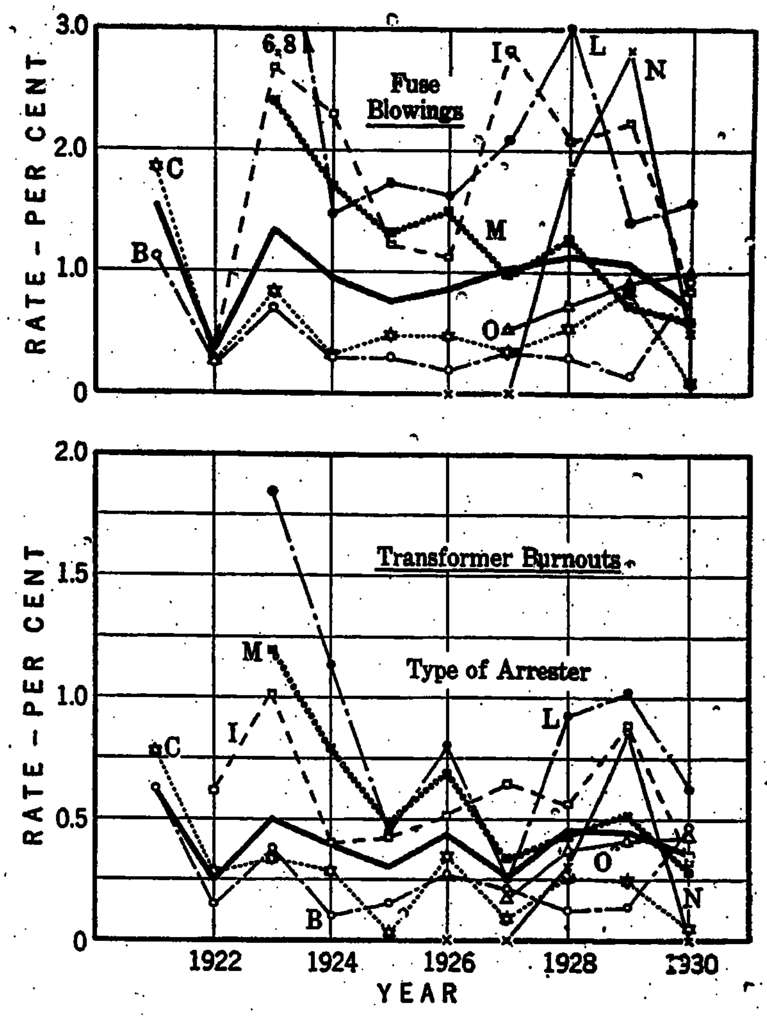

**Fig. 5. (Right) Records of trouble on transformers protected by typical arresters**

Heavy solid line represents average for all arresters on the system

## COMPARISON OF DIFFERENT TYPES OF ARRESTERS

Records indicate that one of the types of arresters (B, Fig. 3) first placed on the market about 20 years ago and withdrawn 10 years later, has not been excelled in its protective efficiency, but its maintenance rate was rather high. It consists of a series of metal gaps with 2 shunting resistors enclosed in a wooden box. At the beginning of 1922 the manufacturers offered valve type arresters in place of the former gap type; these new valve arresters have required about $^{1}/_{3}$ of the rate of replacements that obtain for gap arresters. The ideal valve arrester would be one without a series gap that would discriminate between induced discharges of high frequency and the 60-cycle follow current, opening wide the valve for the former and closing it promptly against the latter, repeating this action year after year without reduction in its protective efficiency.

In recent years several papers have been presented before the A.I.E.E. on the subject of coordination of insulation on transmission lines. These investigations indicate the desirability of similar coordination between lightning arrester performance and the maximum induced discharges to which the distribution transformer windings and bushings are subjected.

## SUGGESTIONS FOR MINIMUM LIGHTNING TROUBLES

1. Use the 4-wire 3-phase system of distribution with grounded neutral.

2. Where transformers or cables are connected to overhead primary mains, install low voltage arresters on the neutral wire and valve type arresters suitable for the Y voltage on the phase wires; avoid duplication within 500 ft, and reduce the number, for Chicago conditions, by $^1/_3$.

3. Use transformers having insulation on the coils and leads that will not deteriorate with age and that will withstand a transient voltage test safely above the voltages to which the transformers will be subjected in service when protected by arresters.

4. If conditions warrant a second ground rod for reducing the resistance of the lightning arrester ground, install also a second ground wire down the pole and connect it to the second ground rod.

5. Select newest transformers for installation in districts of low arrester density and install the older transformers in areas of high arrester density.

6. Require each customer to ground the neutral wire of his house wiring to a water pipe on his premises.

7. Connect the neutral wire of each section of secondary mains to at least 2 ground rods; on long mains install ground rod connections at intervals not exceeding 600 ft.

8. Interconnect, to a reasonable extent, the neutral wires of adjacent secondary mains.

9. Interconnect the lightning arrester ground wire and the secondary neutral wire when the latter is well grounded.

10. Where transformers are connected to primary mains 1,500 ft or more distant from the nearest transformers, install on the pole about 600 ft from the transformers the same lightning arrester equipment as on the transformer pole.

11. Ground the lead sheaths of all underground primary cables.

By following these suggestions and giving the problem continuous engineering supervision, it appears possible to reduce the number of transformer troubles caused by lightning in Chicago, that is fuses blown plus transformers burned out, from 13 cases to less than 1 case of trouble per year per thousand transformers installed.

# II—Experience on a System With High Ground Resistance

By

**T. H. HAINES**
MEMBER A.I.E.E.

**C. A. CORNEY**
MEMBER A.I.E.E.

Both of the Edison Elec. Illuminating Co., Boston, Mass.

FOR YEARS, lightning storms in the territory served by the Edison Electric Illuminating Company of Boston have been accompanied by numerous blown fuses, damaged and burned out transformers, and other troubles, all of which caused many outages to customers with consequent annoyance to them as well as expense to the company. This company distributes electrical energy in 40 cities and towns, embracing 650 square miles in and about the city of Boston. (See Fig. 6.) A total of 325,000 retail customers is supplied from 10,200 distribution transformers. All power customers are fed from 3-phase transformers of which there are 1,500 overhead and 500 underground. Of the single-phase lighting transformers, 7,300 are overhead and 900 underground. In general, the primary distribution system is of the 3-phase 4-wire radial type and operates at 2,300/4,000 volts with the neutral ungrounded. There are approximately 235 such circuits of which about $^1/_5$ of the circuit miles are estimated to be underground.

Prior to 1925, lightning arresters of conventional type had not been used to any extent principally because of the opinion that in order for this equipment to function satisfactorily it was absolutely essential to have low resistance ground connections. Those familiar with New England soil conditions realize that a low resistance ground at the foot of a pole is a rarity. This condition was emphasized in 1917 when the United States Bureau of Standards made a general survey of ground resistance conditions and found that they were worse in New England than anywhere else in the country. (See Bureau of Standards *Publication No. 108,* "Ground Connections for Electrical Systems," by O. S. Peters, June 1918.)

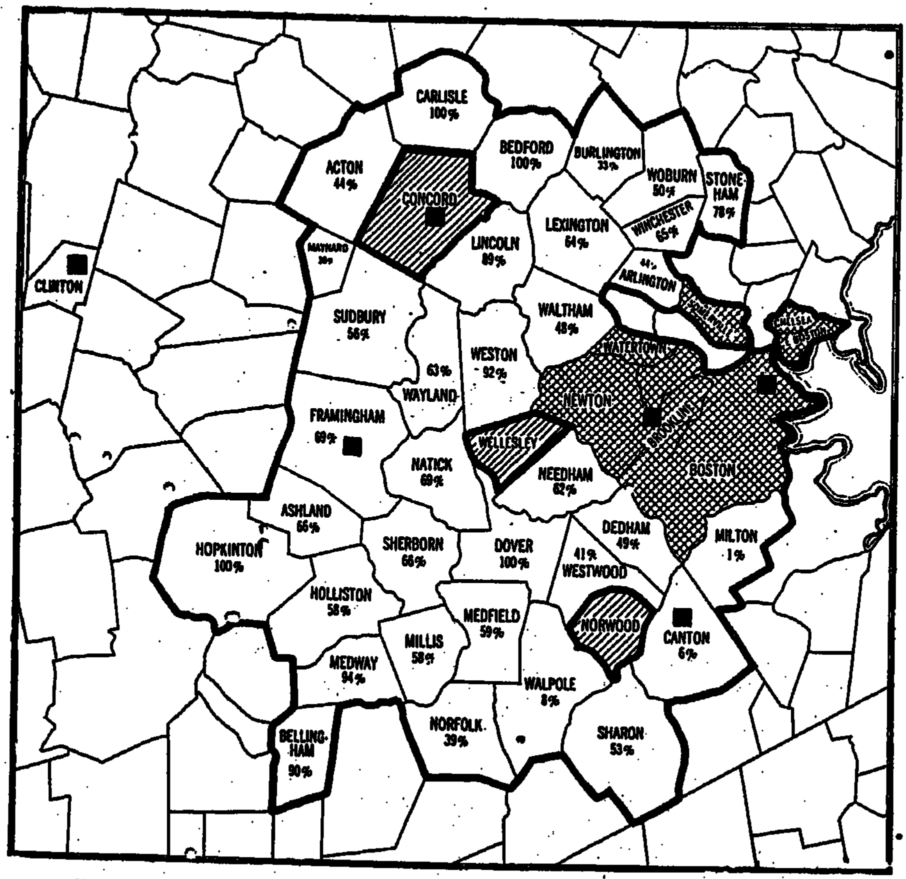

Fig. 6. Territory served by the distribution system of the Edison Electric Illuminating Company of Boston

Single crosshatched areas have municipal distribution. Double crosshatching indicates unprotected area. Black squares indicate observation stations of the U. S. Weather Bureau. Percentages given indicate degree of protection in their respective areas

With the growth of the system, conditions were becoming so acute that early in 1923 it was decided to make a trial installation of several standard lightning arresters notwithstanding the fact that there was little hope of getting what was considered a low resistance ground. The first circuits to be protected were in areas where records had shown

transformer troubles due to lightning to be most severe.

From past experience certain areas in and closely adjacent to the city of Boston had shown a trouble rate about $^1/_3$ of that of the rest of the territory, or less. There is now a total of 3,400 overhead transformers in these areas, none of which is protected by lightning arresters. As this section is more thickly settled than the rest, its comparatively low rate is thought to be due to the shielding effect of structures. As a result, no protection was intended for these areas and consequently they have been eliminated from the study. The protected area in which there are now approximately 5,400 overhead transformers, is shown in Fig. 6.

## METHOD OF CONNECTING ARRESTERS

Lightning arresters of 3 different manufacturers were selected, each having seemingly desirable characteristics; all had porcelain housings, and were rated for circuits of from 4 to 5 kv. Single-phase transformers, which are connected between a phase wire and neutral, were equipped with 2 arresters, one from each wire to ground; 3-phase transformers, which are connected to each of the 3-phase wires, were equipped similarly with 3 arresters. It was planned to equip about 500 transformer installations per year.

As lightning arrester protection was estimated to cost an average of $50 per transformer, it was not deemed economically justifiable, in general, to install the equipment on transformers under 7.5-kva capacity. As the records showed, however, that transformers on dead ends were more susceptible to lightning troubles than the others, it was decided to protect those as small as 5-kva capacity at these points.

The first group of arresters was installed in 1925. Because of the previously mentioned opinion as to the necessity for low resistance grounds, it was decided for the first trial group that lightning arresters would not be installed unless a ground connection of 250 ohms or less could be obtained. Soon after the work was started, however, it was found that even 250-ohm grounds were difficult to obtain. Consequently in order to be able to complete a reasonable number of installations for observation, the limit for ground resistance above which arresters should not be used was raised to 1,000 ohms.

## RESULTS OF STUDY

No attempt was made to analyze operating records until 1927 as the number of installations in service previous to that time was thought to be too small to obtain reliable data. From the procedure established, it may be noted that in any area selected for protection some transformers were protected and some were not. It was thought that in general this practise would give a means of comparing the performance of transformers protected with that of those not protected. Each year previous to the lightning storm season, all arrester grounds were measured for ground resistance; those over 250 ohms were treated with salt and water and/or had additional rods driven in an attempt to lower their resistances.

A summary of data collected for protected and unprotected transformers, arranged by years from 1927 on, is given in Table II. Results for 1927 show that the installation of lightning arresters on certain transformers decreased all types of lightning troubles on those transformers by 40 per cent, and all troubles except those classified as miscellaneous, by 50 per cent.

During 1928 lightning storms were much less frequent than in the previous year resulting in only about half as many transformer troubles as in 1927. The summary of troubles for this year as shown in Table II indicates that the troubles with protected transformers were much less than the troubles with unprotected transformers.

In 1929, as a result of the previous 2 years' experience, lightning arresters were installed at a more rapid rate and ground resistances up to 2,000 ohms for transformers larger than 10 kva were accepted, although as before, salt treatment was given where possible in an endeavor to lower the resistance of such installations. The summary of results for that year (Table II) shows even more strikingly the effectiveness of protection as in this year there was proportionately more than 3 times as much trouble on unprotected transformers as on protected ones. An analysis of troubles by transformer sizes showed that while transformers 5 kva and smaller constituted slightly less than 30 per cent of all the transformers in service, they accounted for more than 50 per cent of the troubles.

By 1930, 3 consecutive years of study had demon-

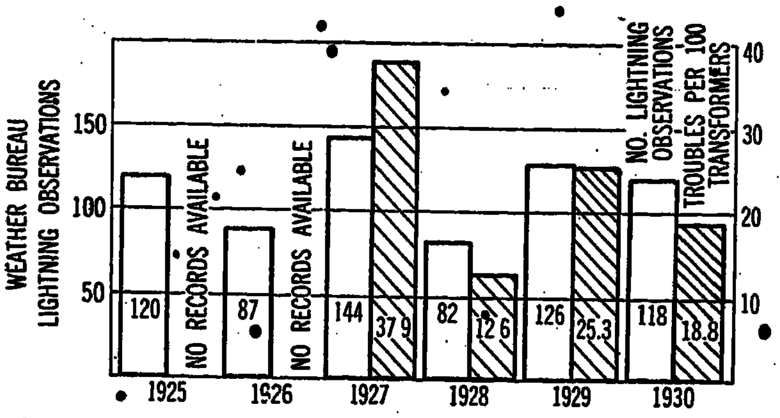

**Fig. 7. U. S. Weather Bureau lightning observations compared to transformer troubles**

strated the effectiveness of the protection afforded by lightning arresters. The fact that proportionately more troubles occurred on transformers of 5 kva and smaller capacity, and that in general the smaller transformers are more remote from maintenance headquarters, together with the improvements shown with increased arrester density, led to the decision that all transformers in towns in the protected area ultimately should be protected.

As a further result of the studies and in an effort to apply the new program most effectively all unprotected transformers where trouble had occurred more than twice in 1929, were equipped with arresters. Also a small group of towns where excessive lightning troubles had occurred were selected and arresters were added to give 100 per cent protection before the 1930 lightning season.

In 1929, as stated previously, it was learned that transformers of small sizes were particularly susceptible to lightning outages. The 1930 analysis brought out the same condition, but more strikingly: Of the total troubles 67 per cent was on transformers of 5 kva and smaller; this group constitutes 28.5 per cent of the total number of transformers.

## DATA CORRECTED FOR STORM SEVERITY

As 100 per cent protection is approached, the means of comparing the effectiveness of the work tends to disappear and a need for some other measure to show the progress being made becomes evident. The United States Weather Bureau records observations of lightning storms from several stations in and about Boston. Lightning observations reported by the bureau have been totaled and called the "storm severity factor"; this factor is used as a divisor to modify the trouble rates in an attempt to render them more comparable. Locations of these observation stations are shown in Fig. 6 while Fig. 7 gives the total number of observations each year compared with the number of transformer troubles in the same year.

Reduction in trouble rate resulting from the application of arresters modified by the storm severity factor, is shown in Fig. 8 plotted against arrester protection in per cent. Extrapolation of the trend curve gives an indication of the improvement that may be expected by further additions of lightning arresters. As may be noted, this trend for the area considered is shown as a straight line. Other curves in Fig. 8 show the reduction in trouble rate for an individual town and for a group of towns; these are given to indicate the effect of complete protection in lowering the trouble rate. These particular towns were selected on account of the severity and frequency of storms in their respective localities.

Using this expectation curve as a basis, it can be shown for this system that the annual saving in cost of maintenance to be expected by the decrease of troubles anticipated from the protection of all the remaining transformers in the protected area, will be sufficient to finance the additional investment required for complete protection. Additional gains will be realized in decreased customer outage and decreased handling and overhead expenses, items not included in the cost analysis.

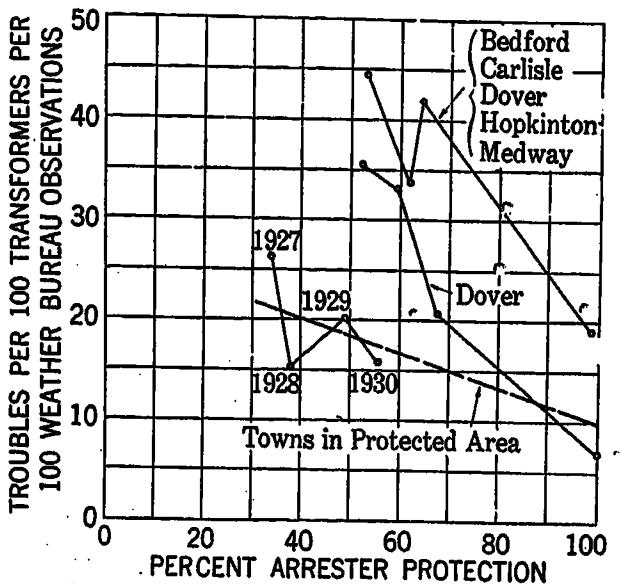

**Fig. 8. Reduction of trouble rate effected by lightning arresters**

## ARRESTER DENSITY AND GROUND RESISTANCE

Studies of the effect of lightning arrester density per unit area and of the effectiveness of various values of ground resistance were begun in 1927 and continued throughout the investigation. Results of these studies are plotted in Figs. 9 and 10, respectively. A distinct improvement as the density increased is indicated by Fig. 9; this seems to check conclusions reached in previous studies. (See "Studies in Lightning Protection on 4,000-Volt Circuits," D. W. Roper, A.I.E.E. TRANS., v. 35, 1916, p. 655; and v. 39, 1920, p. 1895.)

As previously mentioned, the average ground resistance in the area served by this company is high, being over 200 ohms. In Fig. 10 it may be seen that for resistances lower than 100 ohms, decreased resistance makes a definite improvement in the effectiveness of arresters, whereas above that value the effectiveness is not reduced materially by higher ground resistance. The upper horizontal line on Fig. 10 shows the average trouble intensity for unprotected transformers. A comparison of the curves indicates that arresters even with extremely high ground resistances give valuable protection. In the course of early discussion of these data the question was raised as to whether the ground resistance offered to 60-cycle current used for testing might be different from that offered to lightning waves. An investigation made subsequently by one of the lightning arrester manufacturers showed that resistance values offered to lightning waves are appreciably less than those offered to 60-cycle currents. (See "Impulse Characteristics of Driven Grounds," H. M. Towne, *G.E. Rev.*, Nov. 1928.) This may account to a certain extent for the relative effectiveness of ground connections having high 60-cycle resistances.

As stated previously, lightning arresters from 3 manufacturers were used. Records of troubles were segregated and tabulated by manufacturers throughout the investigation. A comparison of these data show that for conditions as found on this system there is little to choose between the different arresters.

During 1930 careful inspections were made of nearly all the transformers where fuses had been blown during lightning storms. Evidence of arcing was found in nearly every case. The arcing seemed to be concentrated on those transformers which were of somewhat ancient design with small primary bushings, insufficient internal clearances, primary terminal boards, etc. Tabulation of the results indicated that transformers made previous to 1910 gave several times as much trouble as those manufactured since then. Inasmuch as previous to this date high-loss iron for the transformer cores was used quite generally, the policy has been adopted of eliminating these old transformers from the system. All other transformers passing through the shop are rebuilt to increase internal clearances and are equipped with modern bushings.

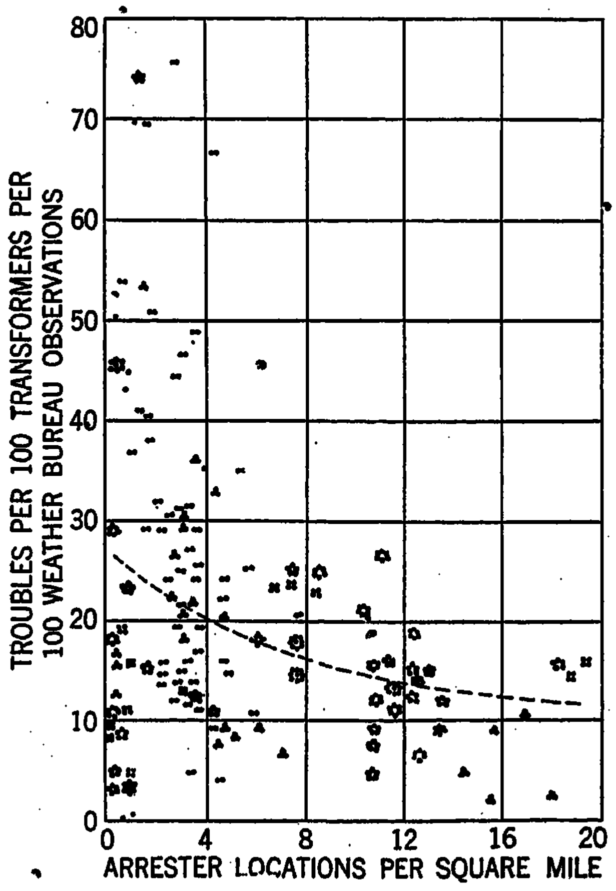

**Fig. 9. (Left) Variation of transformer trouble rate with lightning arrester density, 1927–30**

## SHIELDING EFFECT OF STRUCTURES

During 1930 additional data were obtained which indicated that the shielding effect of structures and other conductors may have a more pronounced effect in protecting transformers and fuses against lightning outage than previously had been recognized. Thus the trouble rate in any area appears to be influenced by a combination of the effects of shielding and arrester density, each of which contributes its share to the final result.

## RESULTS OF 1931 STUDY

While the data for the year 1931 have not been studied carefully on account of lack of time, the summary in Table II shows a marked decrease in the total number of troubles as well as in the trouble rate. Again the rate of trouble on protected transformers is less than half that of the unprotected. The marked decrease in troubles is due in part to the rebuilding of about 25 per cent of the transformers and the removal from the system of most of the small transformers built prior to 1910. It should be noted that the improvement in operation of the protected transformers in general remains the same as in previous years even with nearly all the small trouble-making transformers removed from the system.

## CONCLUSIONS

On the basis of results obtained to date, the following conclusions seem justifiable for this system:

1. Application of lightning arresters to line transformers in areas affected by lightning reduces the trouble rate by about 50 per cent.

2. Variation in ground resistance within the values readily obtainable in this territory has slight effect on the efficiency of arresters.

3. The value of treating grounds or the installation of multiple grounds in an effort to lower resistance is questionable unless by so doing the resistance can be lowered to about 100 ohms or less.

4. Insufficient electrical clearances in the smaller and older transformers are an important source of lightning trouble. Larger bushings and greater clearances are clearly indicated to be necessary features of correct transformer design.

All of the Philadelphia (Pa.) Electric Company

INVESTIGATIONS of lightning troubles have been conducted on the distribution system of the Philadelphia Electric Company since 1921. Their purpose has been to determine: (1) magnitude and nature of trouble in various localities; (2) effectiveness of lightning arresters under field conditions; and (3) ways and means for improving service continuity. Up to and including 1929, studies were confined to the Philadelphia division. In 1930 they were extended to the entire system which includes 6 operating divisions having in service approximately 23,000 aerial transformers.

During the period 1921–29, investigations were confined to the analysis of fuse blowings and transformer failures. Comparisons of trouble on protected and unprotected transformers (reduced to a common basis of troubles per 100 transformers in service) appeared to indicate that lightning arresters were not providing satisfactory protection. This was attributed to the relatively high resistance of the arrester grounds, which average well over 100 ohms.

In 1930, the studies not only were extended to all operating divisions of the system but also were broadened to include many factors which from past experience appeared to be of major importance. Also in 1930 these studies were extended to the territory of the former Philadelphia Suburban-Counties Gas & Electric Company, and of the Susquehanna Utilities Company. This permitted investigations on a variety of types of distribution systems as follows:

1. 2.3-kv, 2-phase, 3-wire, ungrounded.
2. 2.3-kv, 3-phase, 3-wire, ungrounded, Δ-connected.
3. 4.1-kv, 3-phase, 4-wire, grounded, *Y*-connected.
4. 6.6-kv, 3-phase, 3-wire, ungrounded, Δ-connected.

From observations thus far it has been impossible to detect any difference in susceptibility to lightning between grounded and ungrounded systems.

## SUMMARY OF LIGHTNING TROUBLE, 1930–31

During 1930, approximately 5 per cent of the transformers on the combined system experienced lightning trouble. Of these, 68 per cent represent transformer fuse and fuse box trouble, and the remainder transformer (bushing, lead, or winding) trouble. Similar conditions were found to exist in 1931 also. Lightning trouble data for these 2 years are summarized in Tables III and IV.

In the light of these experiences, several different factors which appear to be of major importance to the lightning protection problems as a whole next will be discussed. This discussion is based largely upon experience in the Philadelphia division, for which more complete information was obtained than for the other divisions.

**Table III—Summary of Transformer Lightning Trouble—1930**

| Division | Transformers | | | Troubles per 100 Transformers | | |
|---|---|---|---|---|---|---|
| | No. in Service | Average Size, Kva | Total Troubles | Fuse and Fuse Box | Transformer | Total |

## SIZE AND AGE OF TRANSFORMERS

Trouble was found to decrease with increasing size of transformers (see Fig. 11). The greater trouble on small transformers is believed to be due largely to (1) small clearances between leads and case, and (2) smaller bushings, thus permitting more flash-overs at these points with resultant short circuits. The age of a transformer appears to have but little effect upon its trouble rate except on sizes of 5 kva and less; also the newer transformers are less susceptible to lightning troubles than the older ones. Therefore, a reduction in trouble should result if the smaller transformers be replaced by larger ones or by ones of like size of recent design.

## ARRESTER AND FUSE PROTECTION

Analysis of arrester performance, neglecting transformer size, has shown consistently during the past 5 years that arresters apparently effected little reduction in trouble. However, the same data, when analyzed with respect to transformer size, based upon cases of trouble on various size-groups, indicates that

---

Based upon "Distribution System Lightning Studies by Philadelphia Electric Company" (No. 32-20) presented at the A.I.E.E. winter convention, New York, N. Y., January 25–29, 1932.

transformers having capacities of 15 kva or less were not benefited materially, but that those of more than 15 kva capacity showed a considerable reduction in trouble. (See Fig. 12.) The apparent poor performance of arresters on small transformers may be due to the relatively low voltage breakdown of transformer leads to case resulting from small clearances; the breakdown voltage of the transformer leads may approach too nearly that of the arresters. It is believed this applies particularly to the older transformers.

Fuse size has an important bearing upon the number of fuse blowouts during lightning storms. In the Philadelphia division and in the area served by Susquehanna Utilities Company these troubles were reduced materially by changing from small to large fuses; no appreciable increase in transformer failures resulted from this change. Former practise was to protect against overload by fusing at 1 amp per kva of transformer capacity. At present, fusing against short circuit is general practise throughout the system.

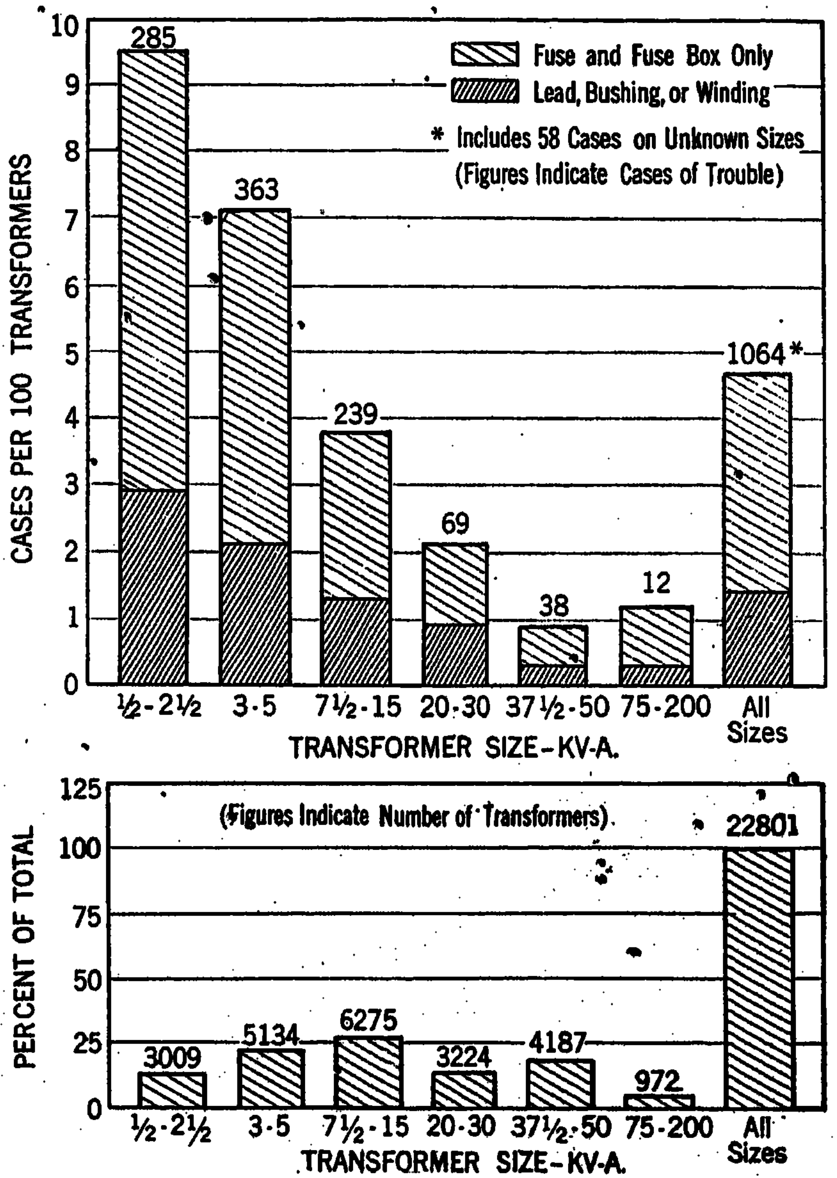

**Fig. 11. Fuse and transformer lightning troubles on aerial portion of Philadelphia Electric Company distribution system (above) compared to number of transformers in service (below)**

LIGHTNING STORM SEVERITY; SHIELDING

Approximately 45 per cent of the total distribution system lightning trouble for 1931, up to September 1, occurred during one storm (July 14) although there were 20 or more other storms during this period. This, with similar experience in previous years, indicates the number of storms to be an unsatisfactory measure of over-all lightning severity for any given year. At present, practical methods for measuring lightning severity are not available. It is desired to stress the need of suitable devices for this purpose.

Regarding "exposed" and "unexposed" locations, thus far it has not been found possible to establish any satisfactory relation between trouble experienced from lightning, and shielding provided by trees, tall buildings, or topography. However, it is felt that this may be a significant factor, since where shielding prevails, less lightning trouble is likely to result.

EFFECT OF GROUND RESISTANCE

Theoretically, the lower the arrester ground resistance the greater will be the reduction in surge voltage while the arrester is discharging. This fact, together with the favorable performance of arresters where ground resistances have been reduced to about 15 ohms or less on this company's 13.2-kv lines, is largely responsible for the effort directed toward improving grounds.

Measurements of single driven grounds widely distributed throughout the system indicated an average ground resistance of the order of 100 ohms. Accordingly, consideration was given in 1931 to the following methods of improving grounds:

1. Salt treatment.
2. Multiple ground rods.
3. Connection to water system.
4. Connection to secondary circuit grounded neutral.

Methods 2 and 4 were experimented with as discussed in the following paragraphs.

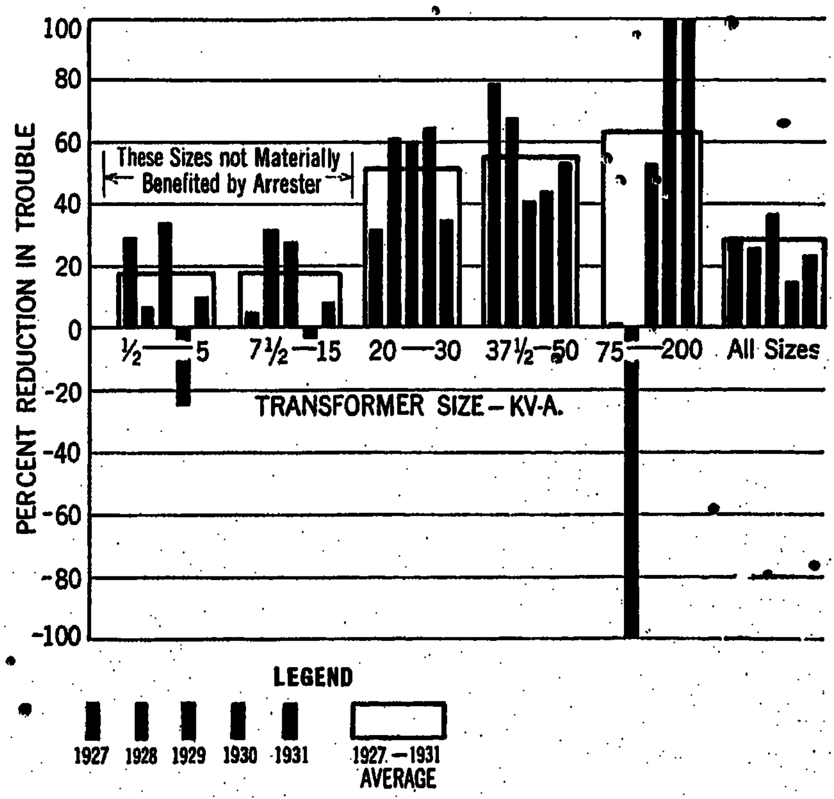

**Fig. 12. Reduction in distribution system troubles effected by primary lightning arresters**

### MULTIPLE GROUND RODS

In northeast Philadelphia where lightning trouble was serious, 345 installations of ground rods in multiple with existing arrester grounds were completed in July 1931. With a maximum of 4 additional rods per installation, it was possible to reduce 45 per cent of the grounds, many of which originally exceeded 50 ohms, to less than 15 ohms; all were reduced to less than 50 ohms. Up to September 1, 1931, 8 cases of trouble had occurred at these locations. Of these 8 cases, 7 occurred where the ground resistances exceeded 15 ohms. Expressed as troubles per 100 transformers, these data indicate only 13 per cent as much trouble where ground resistances were less than 15 ohms, as where ground resistances were higher than that value. However, this experience covers but a very short time and hence the results cannot be considered conclusive.

Multiple rods were installed also in an area outside of Philadelphia where lightning troubles had been even more serious than in the Philadelphia division. In that area 266 installations of multiple rods were completed in June 1931. While essentially the same reduction in resistance was obtained as in Philadelphia, experience in the 2 situations differed to the extent that the trouble rate was the same for ground resistances both above and below 15 ohms. This apparent difference in arrester performance in the 2 areas is believed to be due to the relatively small transformers in the area outside of Philadelphia, averaging about 4 kva in capacity compared with an average of 15 kva in Philadelphia. As previously discussed, studies have shown that but little protection can be obtained for the small transformers.

### CONNECTION TO SECONDARY GROUNDED NEUTRAL

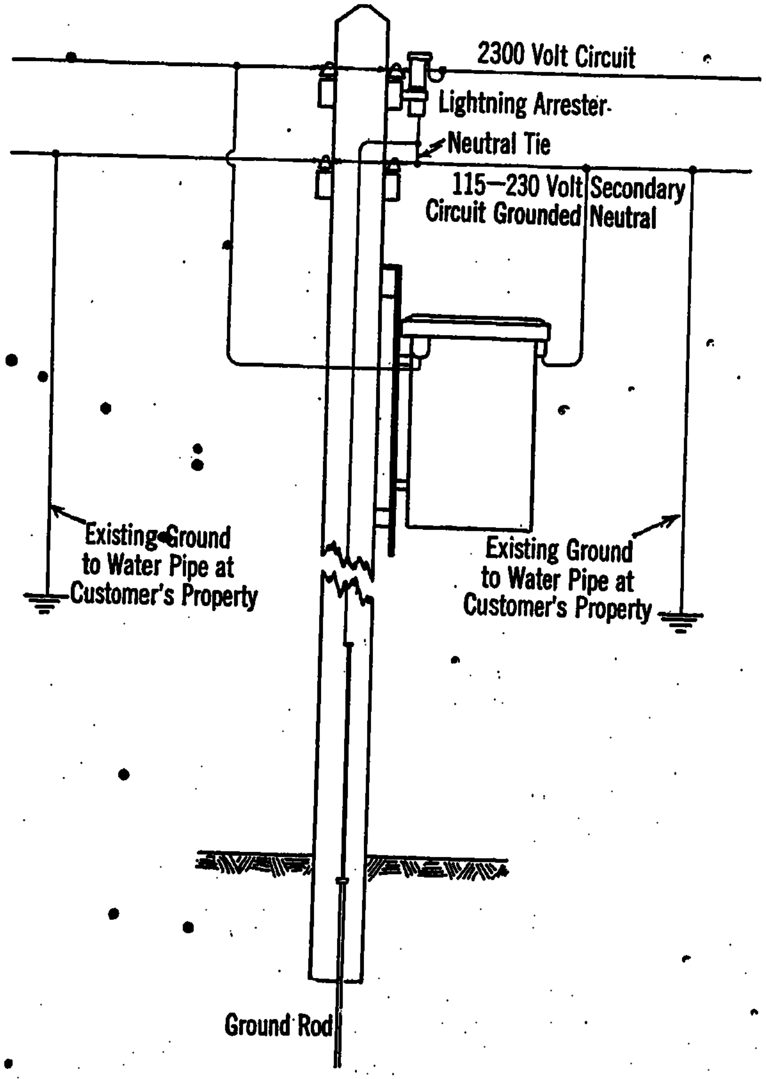
Because of its low cost and added advantage of tending to equalize surge potentials on both primary and secondary sides of transformers during arrester discharges, connection between the primary arrester ground wire and the secondary circuit grounded neutral has been studied. Trial installations of this connection, hereafter called the "neutral tie," were completed early in June 1931 at 151 locations, involving 179 transformers. (See Fig. 13.) For comparative results these were concentrated in an area adjacent to where multiple rods were installed in Philadelphia, and in which lightning trouble had been equally severe. The use of the neutral tie was restricted to locations where the secondary neutral ground resistance measured less than 15 ohms and where the secondary circuit fed 10 or more customers whose service neutrals were grounded to water pipes.

Up to September 1, only one case of trouble, a transformer fuse blowout, occurred at neutral tie locations. This trouble was not accompanied by trouble on the secondary circuit or customers' equipment. Protected transformers in this area without the neutral tie had approximately the same rate of trouble. Unprotected transformers experienced considerable trouble, indicating that this area had been exposed to lightning storms of at least moderate severity. Although this experience over a short period of time indicates the feasibility of the neutral tie, observations over a long time and with a larger number of installations must be obtained before dependable conclusions can be drawn.

Analysis of customer meter trouble due to lightning during one severe storm indicated less trouble on secondary circuits fed from transformers with the neutral tie than on those from unprotected transformers. This indicates the neutral tie did not aggravate secondary trouble and, therefore, imposed no additional hazard on person or property.

### RELATION OF PRIMARY TO SECONDARY TROUBLES

To determine the relative magnitude of primary and secondary system troubles during lightning storms an analysis of these was made for the unusually severe storm of July 14, 1931. Troubles occurring during that storm were selected for study because there was an unusually large number of them and because information concerning them was concentrated in the records. Later the troubles during this storm were found to constitute approximately 70 per cent of the total 1931 primary system troubles in Philadelphia. These troubles together with the estimated number of resulting customer interruptions are summarized in Table V. Correlating the 138 cases of customers' meter trouble with the cases of primary system trouble, shows that only 2 of the former occurred on secondary circuits fed by transformers experiencing primary trouble. Accordingly,



2300 Volt Circuit
Lightning Arrester
Neutral Tie
115—230 Volt Circuit Grounded
Secondary Neutral
Existing Ground to Water Pipe at Customer's Property
Existing Ground to Water Pipe at Customer's Property
Ground Rod

**Fig. 13. Method of interconnecting arrester ground wire and secondary circuit grounded neutral, Philadelphia division**

secondary circuit trouble must be due largely to disturbances originating on that circuit.

It is evident from the causes of customers' interruptions that greater over-all improvement in service continuity may be accomplished by attacking the primary rather than the secondary situation. However, from the viewpoint of the individual customer, interruptions from secondary trouble are equally as important as those caused by primary trouble. Therefore, efforts should be directed also toward reducing the secondary troubles.

## ANALYSIS OF CUSTOMER-HOUR INTERRUPTIONS

Primary circuit and individual transformer interruptions exceeding 5 minutes in duration throughout Philadelphia and suburban divisions in 1931 to September 1 were analyzed to determine the relative magnitude of (1) those during lightning storms and those during other periods; and (2) those due directly to lightning disturbances and those due to other causes, such as wind, trees, etc., during lightning storms. Results of this analysis are shown in Fig. 14 where interruptions are expressed in customer-hours and classified according to character of trouble. These results show that (1) of the customer-hour interruptions exceeding 5 minutes from all causes, more than 80 per cent occurred during lightning storms; and (2) of those during lightning storms, at least half are due directly to lightning disturbances. It appears, therefore, that protection of distribution systems against lightning is of major importance in bettering service continuity.

**Table V—*Primary and Secondary Trouble and Estimated Customer Interruptions Due to a Severe Lightning Storm**

| Classification of Trouble | Number of Cases | Estimated Customer Interruptions |
|---|---|---|
| **Primary System (2.3 kv)** | | |
| Transformer fuse and fuse box | 69 | 4,140 |
| Transformer winding | 30 | 1,800 |
| Transformer lead | 27 | 1,620 |
| Primary wires down | 27 | 16,200 |
| | 153 | 23,760 |
| **Secondary System (115/230 volts)** | | |
| Customers' service fuses blown | 1,200 | 1,200 |
| Cusomers' defective apparatus, appliances, cords, and wiring | 300 | 300 |
| Meters damaged | 138 | 138 |
| Outside (external to service connections) | 90 | 90 |
| Service pipes | 2 | 2 |
| | 1,730 | 1,730 |

* For Philadelphia division only; excludes service lost due to circuit interruptions at substations.

## SUMMARY AND CONCLUSIONS

From the foregoing experience, the following conclusions are reached:

1. Annually about 5 per cent of the 23,000 aerial distribution transformers experienced trouble in some degree due to lightning. Small transformers have been found more susceptible to lightning disturbances than large ones. As far as practicable, the larger transformers should be used, or the older units replaced with more recent ones of the same size.

2. Differences in susceptibility between transformers of different sizes must be recognized when analyzing arrester performance. Observations over 5 years show little benefit from arresters when considering transformers of all sizes collectively. However, taking size into account, these same data indicate that arresters afforded little benefit to those of 15 kva and less capacity, but substantial benefit to the larger sizes.

3. Many factors influence lightning trouble on distribution systems. It is important to consider all of the major ones if reasonable conclusions are to be reached. Also, to permit comparisons with other studies, it is important to have data reduced to a common basis. One method is to compare performance per 100 transformers.

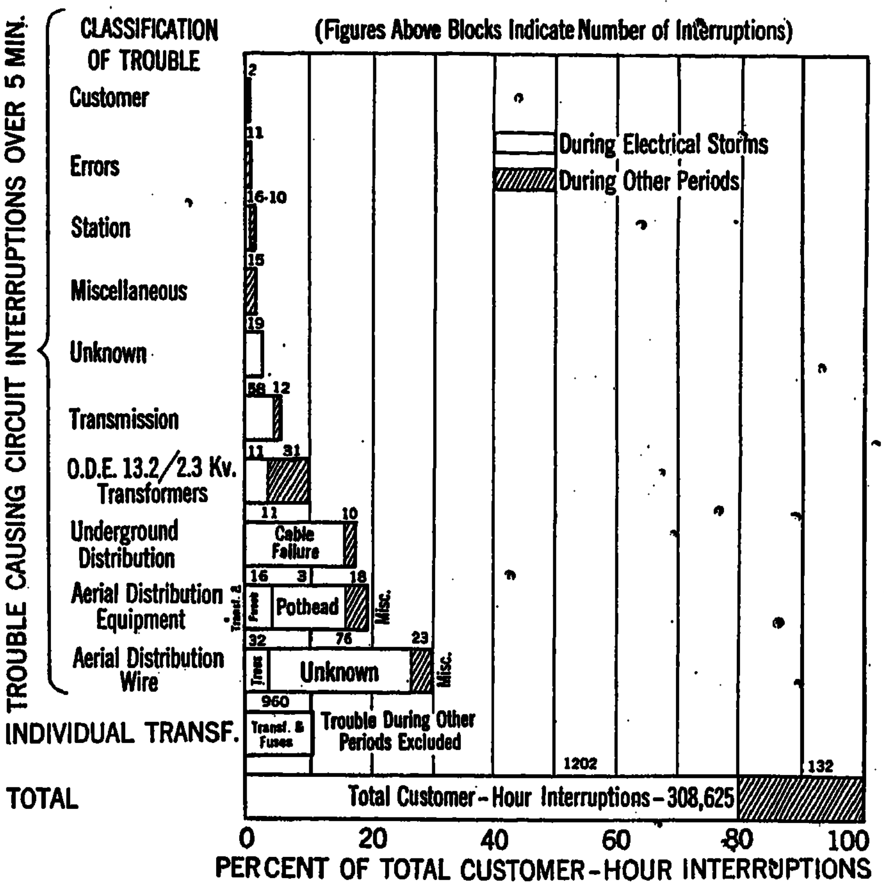


Fig. 14. Estimated customer-hour interruptions due to primary distribution system outages for the first 8 months of 1931; estimates are for Philadelphia and suburban divisions

4. Because of the many factors involved, it has not been possible thus far to determine whether there is a material difference in susceptibility to lightning trouble on grounded and ungrounded systems.

5. Low ground resistance, which theoretical and field studies show to be essential to effective arrester performance, may be obtained at low cost by connecting the arrester ground wire to the secondary circuit grounded neutral; however, where this is done, secondary neutrals should be grounded effectively. Limited field experience shows that this method furnishes satisfactory protection against transformer failure without introducing additional troubles on the secondary system.

6. Customer interruptions from trouble on the primary system far exceed those from trouble on the secondary system. Therefore, major improvement in service continuity can be accomplished best by attacking the primary situation. However, service reliability as measured by the customer is independent of the source of trouble, and consequently improvements on the secondary system cannot be neglected.

7. The number of customer interruptions of a duration less than 5 minutes greatly exceeds those of more than 5 minutes. However, based upon customer-hour interruptions, the latter greatly exceeds the former.

8. The majority of customer-hour interruptions from all causes occur during electrical storms. Of these, this study shows that at least half are directly attributable to lightning disturbances.

9. In the interest of improving service continuity, lightning protection of distribution systems has been found to be of major importance and can be justified economically only from this point of view. Minimizing inconveniences to customers, although of intangible value, nevertheless is highly important and should be carefully considered when establishing policies and practise in solving the lightning protection problem.

# Kaplan Turbines at Safe Harbor Hydroelectric Plant

**One of the numerous features of more than usual interest of the Safe Harbor hydroelectric development is the use of Kaplan turbines having automatically adjustable blades. This type of turbine is used in all of the 6 units of the initial installation, each rated at 42,500 hp under a rated head of 55 ft. Engineering studies in connection with these units required the construction of a new hydraulic laboratory for testing model turbines.**

G. W. SPAULDING
MEMBER A.I.E.E.

Both of the Safe Harbor Water Power Corp., Baltimore, Md.

MANY new and interesting problems arose in connection with the design and installation of the Safe Harbor turbines. As in any pioneering development of this magnitude, an unusual amount of experimental and engineering study was necessary involving not only the hydraulic and mechanical design of the plant but affecting the structural and electrical design as well.

Limited experience in this country with propeller type turbines caused the Safe Harbor management to feel that certain important operating and engineering information was essential to justify a large expenditure in this comparatively new type of turbine. This feeling was intensified by the fact that the manufacturers had to build wheels considerably larger than had been built before. Furthermore, each of the various manufacturers had offered for consideration several different designs for which no comparative data as to cavitation limitations were available.

Final design of the power house structure depended upon the decision as to the elevation of the turbine runner. The position of the runner with respect to the tailwater elevation would affect materially the power rating of the turbine as limited by cavitation; obviously the economics of the power house substructure and excavation could be determined only after the power limits of the various runners were known. The absence of a hydraulic testing laboratory in this country in which cavitation tests could be made led to the construction of such a laboratory at Holtwood, Pa., adjacent to the Holtwood hydroelectric plant.

### WHY KAPLAN TURBINES WERE ADOPTED

During the early engineering studies an investigation was made of the various types of turbines suitable for the Safe Harbor development which has a relatively low operating head, limited storage, wide fluctuations in river flow and operating head, and where peak load rather than base load is of prime importance.

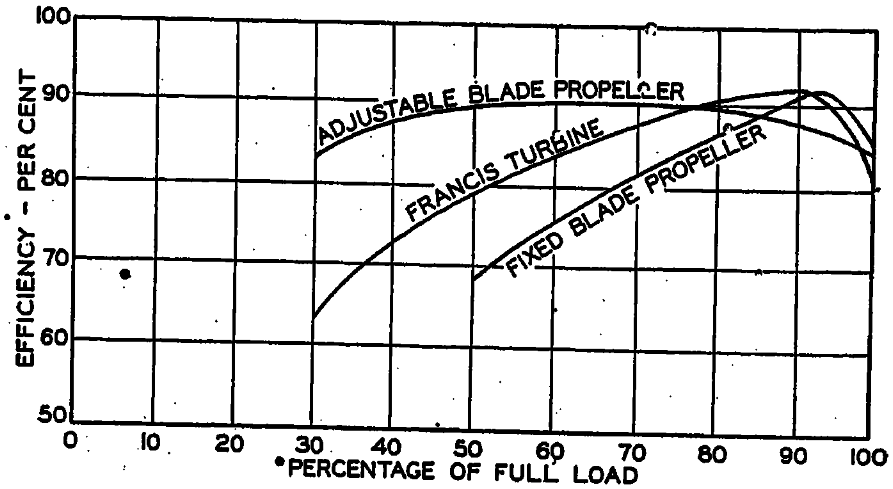

**Fig. 1. Comparative efficiencies of 3 types of turbines**

9,500-hp turbines operating under a head of 38 ft; adjustable blade propeller running at 164 rpm.; fixed blade propeller, 150 rpm; Francis turbine, 100 rpm

Appreciable savings in the cost of power house structures were found possible by using the propeller type of turbine of either the fixed or adjustable blade type. Further savings in the cost of the electric generators were obtainable with propeller turbines because their higher speeds permitted the use of smaller and consequently lower cost generators and direct connected exciters. (See "Hydraulic and Electrical Possibilities of High Speed, Low Head Developments," by Jessop and Powel, A.I.E.E. TRANS., v. 50, 1931, p. 114–9.)

The automatically adjustable blade propeller turbine has certain additional advantages over the fixed blade propeller type: It has a high efficiency over a greater range of loads (see Fig. 1); it can be operated considerably above its normal power rating for short periods of time without an appreciable loss in efficiency; it has materially greater output when operating under reduced heads; it is more stable when operating at part loads. However, on account of the additional mechanism required for blade adjustment, Kaplan turbines are more expensive, both in first cost and in maintenance.

---

Based upon "Safe Harbor Kaplan Turbines" (No. 32-124) to be presented at the A.I.E.E. Middle Eastern District meeting, Baltimore, Md., October 10–13, 1932.

The final decision to use Kaplan turbines in *all* of the initial units, rather than using 1 or 2 Kaplan units and fixed blade propeller turbines for the others resulted from a consideration of the operating requirements of this plant. With a run-of-river plant such as Safe Harbor where the maximum discharge of the initial 6 units will be approximately 50,000 cfs, which flow is available for only about 3 months in an average year, the plant obviously will operate as a peak load plant for the greater part of the time. Such operation involves rapid changes in load. During extreme low-flow seasons, when the reservoir will be drawn down on a periodic schedule, there will be a wide variation in the operating head on the plant. When the normal river flow is less than the usable flow through the plant, water is valuable and high operating efficiency at part load is desirable, for water thus saved replaces steam capacity as well as steam energy on the system.

High part-load efficiencies are particularly important on a system where the spare capacity may be carried at the hydro plants. Furthermore, the Safe Harbor plant soon will be the point of interconnection of several major electric systems and undoubtedly there will be periods when split bus operation will be expedient. With such operation Kaplan turbines are the more economical. Maximum efficiency at full rated load is not essential, since during low river flow rated output would be required for but short periods, while at high river flow, when there is an abundance of water, efficiency is not important. Maximum output for short periods and particularly during flood conditions when the back water materially reduces the operating head at the plant is of particular value. Maximum operating economy and flexibility could best be obtained by using turbines all of the Kaplan type. Certain further advantages always accrue through the use of a single size and type of unit in any plant as it requires a minimum of spare parts to be carried, and minimizes hazards from operation and maintenance.

## DESCRIPTION OF UNIT

A cross section through one of the Safe Harbor turbines is shown in Fig. 2. The runner of the turbine is 220 in. in diameter and has 5 blades. These blades can be rotated about a horizontal axis from approximately a horizontal position for no load operation, to an angle of 30° for maximum loads. The throat ring is spherically shaped to permit this movement with a minimum of clearance between blades and ring, reducing the amount of leakage.

Operating mechanism for changing the blade angle position is located in the hub and hollow shafting of the wheel. Each blade is connected through a link to a main head in the runner hub which is connected by an inner shafting to a large "servo-motor" located just below the unit thrust bearing. Oil pressure obtained from the main governor system is carried to this servo-motor through the "Kaplan head" (on the top of the generator shaft) from the operating valve shown at the right of the main unit. An actuating rod connects the wicket gate operating ring with this valve to maintain a definite predetermined position of runner blade for each wicket gate opening. The correct relationship between gate opening and blade angle was found from tests, and is maintained by a specially shaped cam interposed in the actuating rod between the gate operating ring and the runner blade operating valve. This cam can be changed readily for variations in operating head inasmuch as to maintain best efficiency requires a different relationship for each head.

The intake section of the unit has a horizontal floor constructed at the same elevation as the river bottom in the forebay; side walls are parallel and the roof is bell shaped at the entrance. The center line of the turbine was offset from the center line of the intake 2.0 ft for reasons discussed later. The elbow draft tube has a V-shaped roof toward the discharge end, and an appreciable angle of upturn in the horizontal leg to reduce to a minimum the amount of tailrace excavation.

## HOLTWOOD HYDRAULIC LABORATORY

The hydraulic test laboratory at Holtwood, Pa., was designed for testing model turbines 16 in. in diameter (approximately $^1/_{14}$ the size of the actual Safe Harbor units) with complete wheel setting and water passages including intake, scroll case, wheel casing, and draft tube, under a range in test head varying from 4 to 60 ft. For cavitation tests the

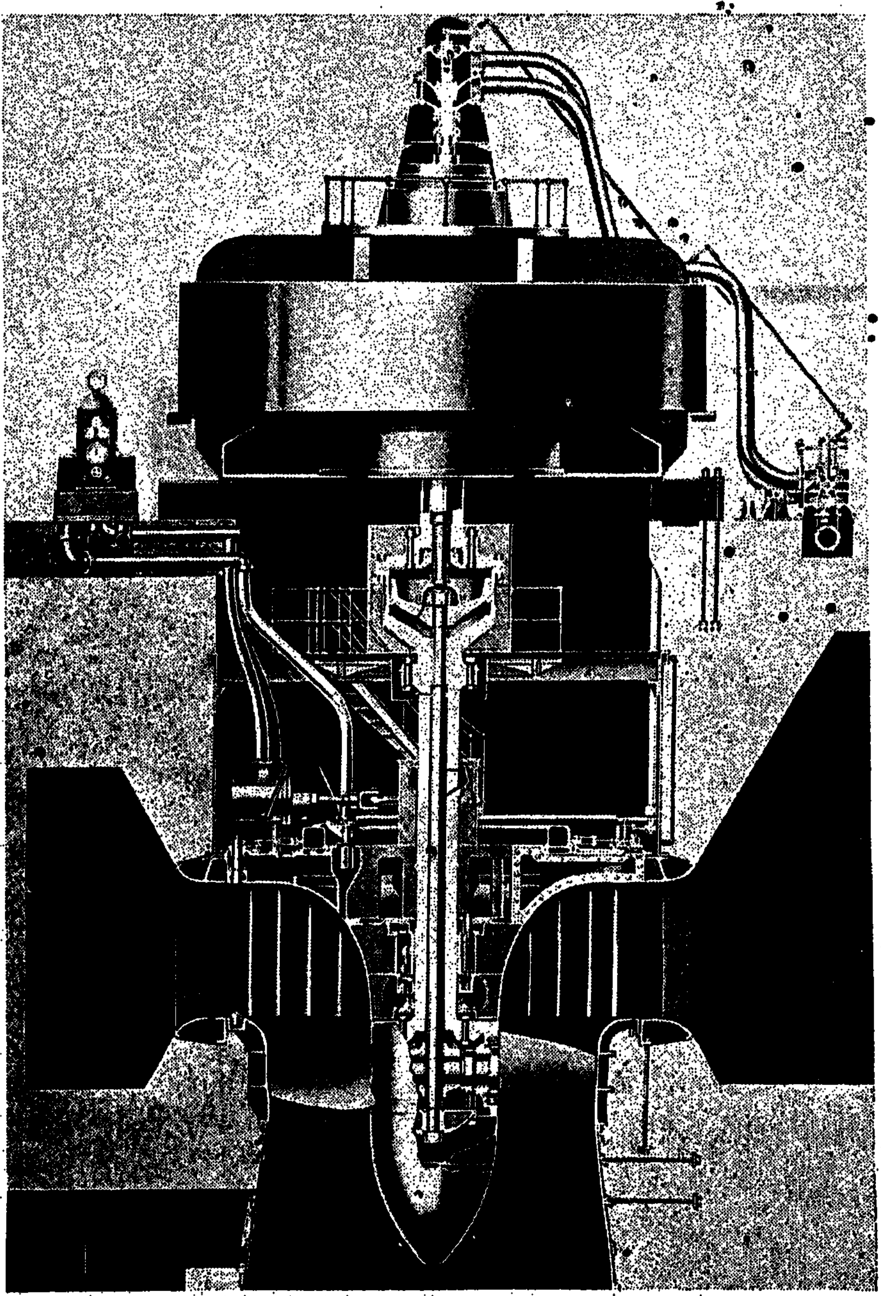

Fig. 2. Cross-section through a Safe Harbor turbine

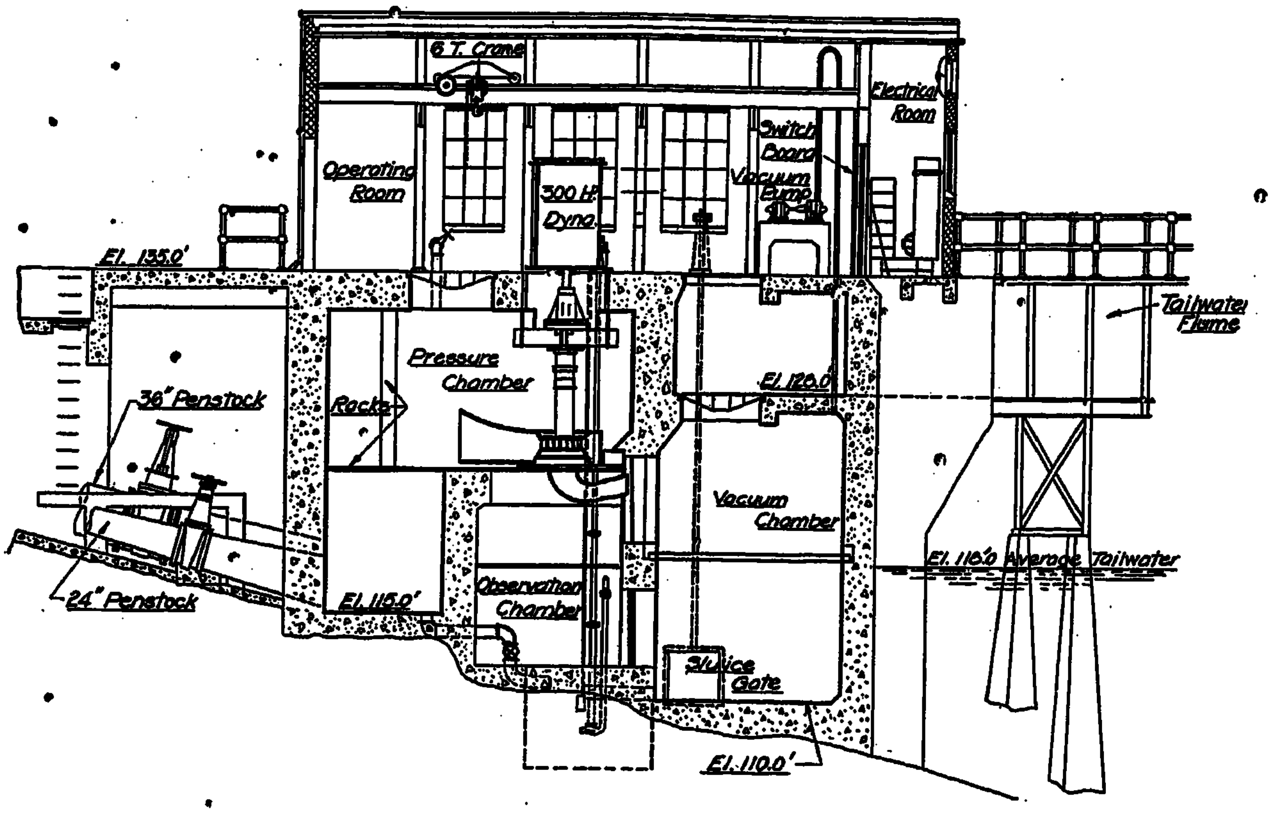

**Fig. 3. Longitudinal section of Holtwood hydraulic laboratory**

draft head may be varied from approximately 10 ft pressure head to 10 ft suction head. A cross-sectional view of the laboratory may be seen in Fig. 3.

The maximum head at the Holtwood plant is slightly less than 60 ft, but since, for cavitation tests it is necessary to vary the suction head over a wide range while holding the total head the same, it was found impossible to get the desired range of heads by using the available drop between the Holtwood forebay and tailrace. A high-head tank therefore was built, into which water can be pumped to an elevation approximately 20 ft above the normal level in the Holtwood forebay, for which purpose a 20,000-gpm constant-discharge pump is used. The water in excess of the amount required in the laboratory is bypassed back into the Holtwood forebay by means of a sluice gate operated by remote control from the main laboratory. By manipulating this sluice gate any desired forebay elevation may be quickly obtained and held constant. From this tank the water flows through a 36-in. penstock to the pressure chamber in the laboratory. After entering, the water must pass through a series of baffles which remove whirls and eddies and insures uniform velocity distribution as the water approaches the intake passages of the turbine. The pressure chamber was designed sufficiently large to accommodate the complete wheel setting. Water passes from the draft tube into a vacuum chamber, so called because a vacuum pump connection permits operating this chamber under either positive or negative pressure as required. The water finally discharges through a sluice gate at the bottom of the vacuum chamber, or may be allowed to enter the chamber above the vacuum chamber from which a flume carries it to a sharp-crested weir.

Because of the wide range required in tailwater elevation, it was impractical to use a weir regularly for measuring the laboratory discharge. A 36 x 15-in. Venturi meter was installed in the main penstock for measuring the water flow; connections to this Venturi meter were brought into the laboratory so that the discharge may be measured in the main laboratory.

Power developed by the test turbine is absorbed by an electric dynamometer mounted on the laboratory floor above the pressure chamber, rated at 300 hp when used as a generator, but also designed to develop 225 hp for operation as a motor for proposed pump tests. This dynamometer was designed specially for this installation and is the first one ever made for vertical mounting. Electrical output from the dynamometer is dissipated in grid resistors.

To facilitate the study of cavitation, the laboratory was laid out to permit visual observation of the water flowing in the draft tube just below the model runner. This has been accomplished by installing small glass windows in the tube. A chamber around the draft tube affords a point of observation for watching the formation of cavitation and the general behavior of water in the vicinity of the runner.

## Cavitation Limit of a Turbine

As previously stated it is of utmost importance to place the turbine runner at the proper elevation with respect to the tailwater surface. If any type of waterwheel is too high above the tailrace, the vacuum formed under the runner blades may cause cavitation, which can result, in addition to a serious loss of efficiency, in the destruction of the runner and draft tube by pitting. Pitting is probably due to a combination of erosive and corrosive action.

Cavitation starts when the absolute pressure at any point in the water column approaches the vapor pressure of the water, which pressure is, of course, very near absolute vacuum. In propeller turbines the velocity of the water is maximum and consequently the pressure minimum where the water passes through the runner. The exact location of minimum pressure depends upon the runner design. If this low pressure is below the vapor pressure at any point along the blade surface, the water will have a tendency to leave the surface of the blade forming a void; such voids will be filled quickly with a mixture of water vapor and air removed from the adjacent water by "cold boiling." The surface of separation between the flowing stream and the eddying region left by the separation may be shown theoretically to be essentially unstable; hence, sudden breakdowns of the cavities rapidly recur, having the effect of continuing explosions, resulting in intense hammer action in the pores of the metal. Eventually such action erodes the surface of the runner blades. In addition to this erosion it is probable that oxygen, which is released readily from solutions at very low pressures accumulates along the surface of the runner blades, and attacks the steel surfaces, especially where the metal has been attacked previously by erosion.

Cavitation can be practically eliminated by setting the runner sufficiently below the tailwater level to insure that the minimum pressures along the blade surfaces are well above the vapor pressure. For economic reasons it is important to determine accurately the maximum elevation at which the runner may be set so as to reduce to a minimum the expensive excavation work for the draft tube and tailrace.

Tests on a complete model of the Safe Harbor intake, scroll case, wheel setting, runner, and draft tube were made to determine within close limits the highest elevation at which the runner could be set without danger of serious cavitation for the maximum turbine power desired. Fig. 4 shows the results of a typical test made for determining the value of draft head at which cavitation starts. Efficiency, power, and discharge of the turbine have been plotted against a coefficient called Σ (sigma). The term Σ first introduced by Professor Thoma of Germany is derived as follows:

Theoretically cavitation starts when the absolute pressure on the runner is equal to the vapor pressure of water; therefore

$$H_B - H_D - \frac{\Sigma V^2}{2g} = H_v \qquad (1)$$

where

$H_B$ = Barometric pressure in feet of water at the surface of the tailwater

$H_D$ = Draft head (elevation of runner minus elevation of water surface in tailrace)

$\Sigma$ = Coefficient

$\frac{V^2}{2g}$ = Velocity head at the blade surface

$H_v$ = Vapor pressure of water

$\frac{V^2}{2g}$ varies directly with $H_T$, the total net head on the runner.

Therefore eq. 1 may be written

$$\Sigma = \frac{H_B - H_D - H_v}{H_T} \qquad (2)$$

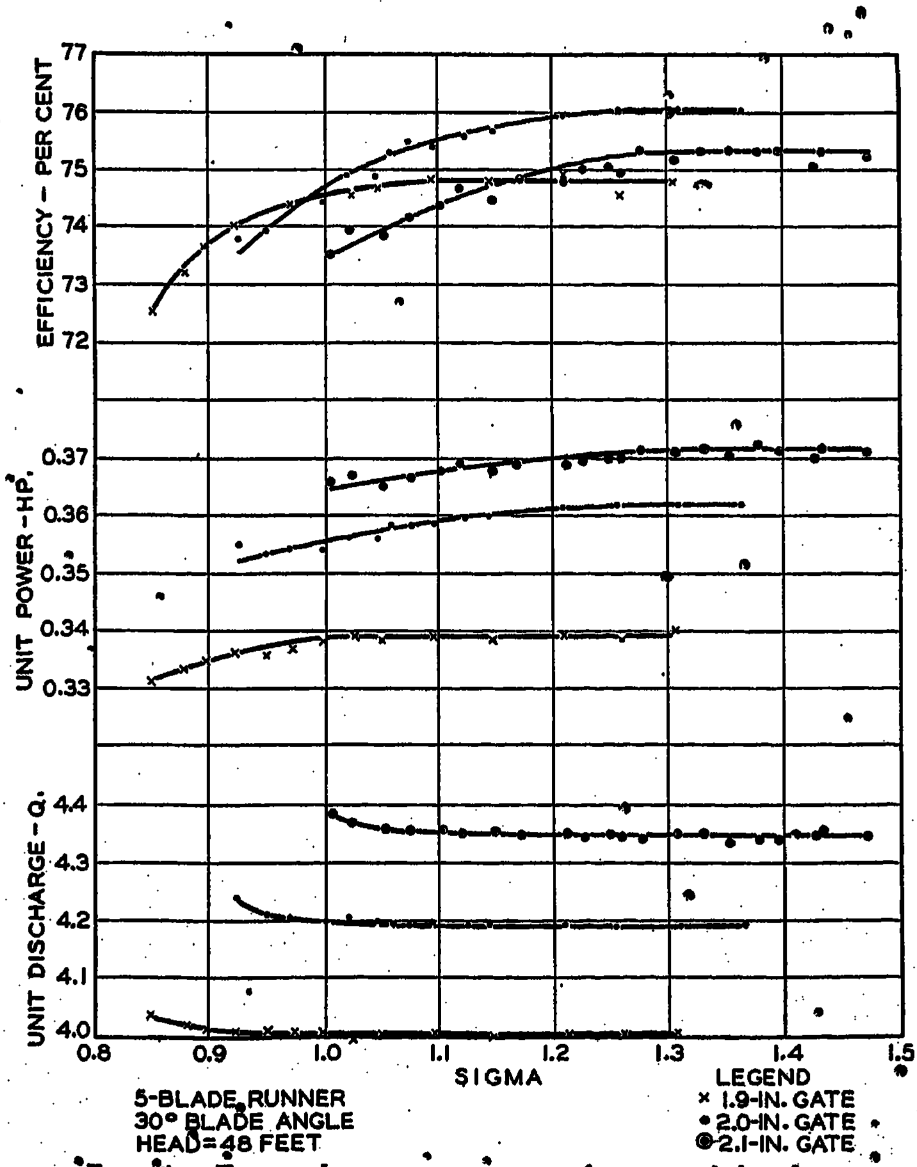

**Fig. 4. Typical cavitation curves for a model turbine**

Laboratory procedure in determining the cavitation limit for a definite blade angle and gate opening was to start with a high tailwater elevation and make a series of tests with gradually decreasing tailwater level maintaining for each series a constant total head and a constant speed. The value of Σ at which efficiency and discharge were found to break, was taken as the cavitation limit for that particular speed, head, and gate opening. Similar tests were made for each combination of head, gate opening, and blade angle. From the results it was possible to predict the cavitation limit of a model runner for various operating combinations of draft head and total head. From an operating standpoint it was essential to establish the limits of power output for a wide range in both draft head and total heads.

## Model Tests of Draft Tube Design

Correlated with the study of the cavitation limits of a turbine, and the economics of determining the proper runner elevation, is the problem of draft tube design. A draft tube with the shortest vertical section usually will be the least expensive, as minimum excavation will be required not only under the power house substructure but also in the tailrace below the power house. A review of European experience together with theoretical considerations of water velocities through a Kaplan runner led to a decision in favor of an elbow type of tube.

Each of the turbine manufacturers submitted alternate designs of elbow tubes, all of which were tested in the Holtwood laboratory with the Safe Harbor model runner, to obtain comparative data on the relative efficiencies and operating characteristics. These tubes differed in the following general features of design:

1. Angle of flare in the vertical section just below the runner.
2. Length of the vertical section (distance between centerline of runner and lowest point of the tube).
3. Location and area of the draft tube "throat."
4. Shape and angle of divergence near the discharge end of the horizontal section.

The final design chosen (see Fig. 5) was determined not only from a consideration of the maximum efficiencies obtained, but also with due regard to the shape of the horsepower-efficiency curves, in order to obtain a curve as flat as possible for each blade angle position, thereby eliminating any possibility of instability resulting from sudden changes in load. An appreciable amount of excavation was saved by turning the whole tube upward through an angle of 9°; it was found that this could be done without sacrificing either efficiency or power.

## MODEL TESTS OF SCROLL CASE DESIGN

A series of scroll case tests were made in the laboratory, before deciding upon the final design, to determine whether any advantage is realized by offsetting the center line of the runner shaft from the center line of the intake, thereby increasing the cross-sectional area of the scroll and reducing the velocity of the water. The results indicate that if for the unit spacing used at Safe Harbor, a speed ring with a relatively large diameter was used, a quite noticeable saving in efficiency and power could be obtained; if, however, the fixed guide vanes of the speed ring were of narrow proportions and the speed ring of smaller diameter, no improvement was found in either efficiency or power.

Scroll cases of the Safe Harbor turbines were designed eccentric, however, even though the speed rings were of relatively small diameter. This decision was made to permit maximum flexibility in the design of the wheel settings for all future units of the plant.

## POWER AND EFFICIENCY TESTS

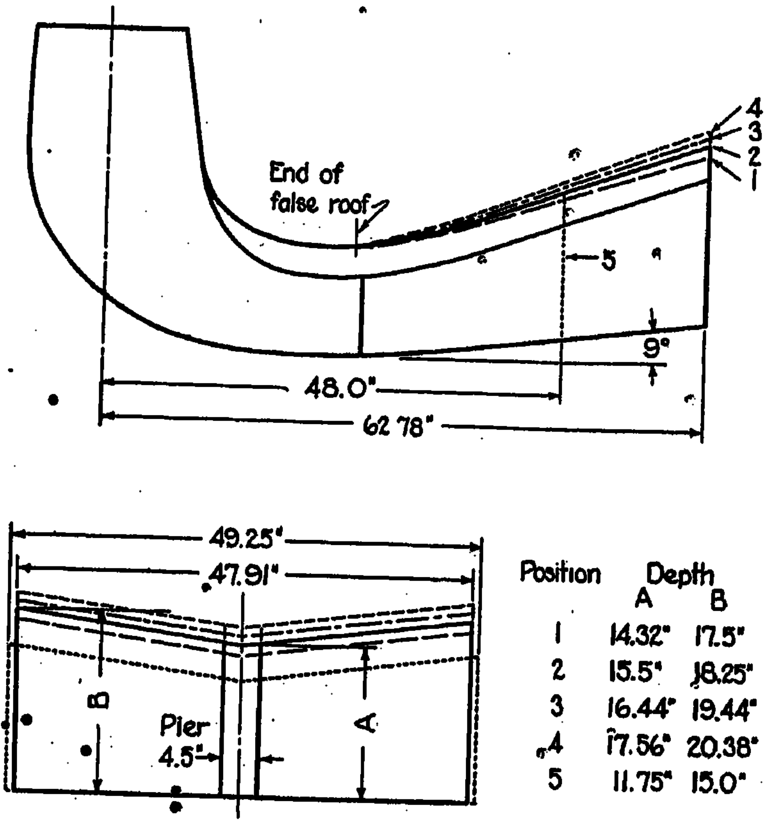
Comparative power and efficiency tests on each of the numerous turbine designs submitted were made at the Holtwood laboratory, all tests being made with a complete turbine setting, including intake, scroll case, and draft tube. These tests were made under a head approximately equal to the field head at Safe Harbor (about 50 to 55 ft) and in each case were conducted in the presence of a representative of the manufacturer whose runner was under test. At the completion of the tests the manufacturers were given the opportunity to revise their guarantees of power and efficiency on their respective turbines. Some of the guarantees for the final Safe Harbor units are shown in Fig. 6.

Curves giving the results of a typical test are shown in Fig. 7. The range in values of $\Phi$ covered corresponds to a variation in head of from 32 to 60 ft, although the actual testing was done under a constant head and varying speeds. Tests were made at various blade angles to obtain an envelope curve representing the maximum efficiency obtainable for the proper operating relationship between blade angle and wicket gates; as previously described this relationship is maintained on the actual units by means of a cam in the blade operating mechanism.

## FIELD TESTS

To insure that the units are properly adjusted and are operating to give the best possible efficiency, numerous field tests and inspections were planned. A small amount of cavitation probably is permissible since the steel blades of the turbine are quite shock-resistant; therefore it was decided to operate the units slightly beyond the point where cavitation started in the laboratory, and study carefully the effect on the runner blades and draft tube.

During the first few months of operation the turbines were inspected about every 2 weeks. Now that the plant has been in operation some time, these inspections are made about every 6 weeks on each unit. It has been found that on certain portions of the runner blades paint was removed. In addition a small area on both the top and bottom blade surfaces at the leading edge near the periphery seemed to be subject to local cavitation. Minute hollows and reversals in curvature attracted cavitation, and eventually pitting took place. However, by slightly reshaping the leading edge of the blade so that it was sharper, and making an exceedingly gradual transition from the nose to original blade surface from 6 to 8 in. back from the leading edge, this local cavitation was largely eliminated. This area probably always will be susceptible to cavitation, and consequently it is of the greatest importance to have a very smooth surface, free from reversals in curvature. One unit



| Position | Depth A | Depth B |
|---|---|---|
| 1 | 14.32" | 17.5" |
| 2 | 15.5" | 18.25" |
| 3 | 16.44" | 19.44" |
| 4 | 17.56" | 20.38" |
| 5 | 11.75" | 15.0" |

**Fig. 5. Various modifications of the Safe Harbor draft tubes studied at the Holtwood laboratory**

Dimensions are for the model tube

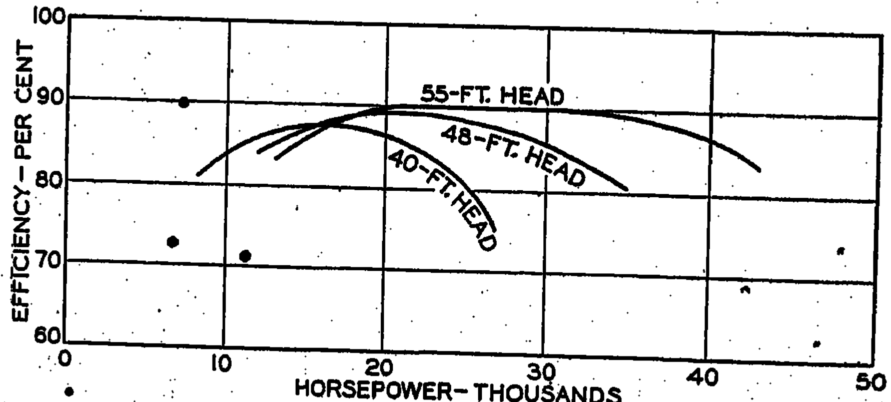


**Fig. 6. Guaranteed horsepower-efficiency curves for a Safe Harbor turbine running at rated speed of 109.1 rpm**

was held at a power output limit well below the point where cavitation started on the model. The paint erosion on this unit was less than on the other units, but the local pitting was of about the same magnitude, and in the same place.

On the underside of the blades near the trailing edge, an area has been attacked by slight cavitation of a magnitude sufficient to remove the paint, but as yet there is no indication of pitting. It is interesting to note that rust has covered these areas in spite of the cavitation.

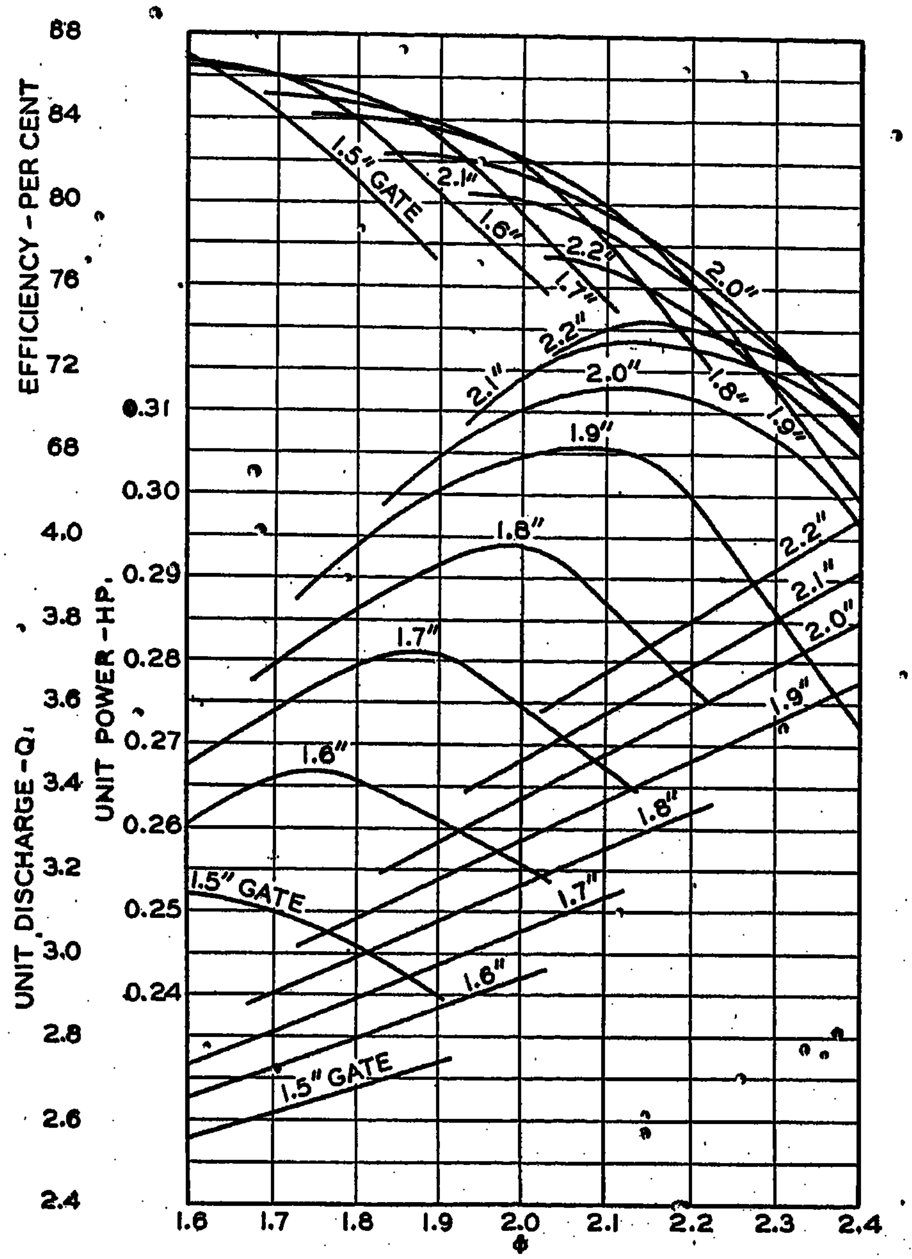

**Fig. 7. Typical efficiency curves computed from test results on a model turbine; blade angle 22°**

Φ is the ratio between peripheral speed of the runner and spouting velocity for the head in question

To establish the most efficient relationship between gate opening and blade angle, it is not necessary to measure the actual efficiency or discharge; it was decided to establish this relationship by the use of an index method. At various points in the scroll case and on the wheel setting 7 piezometers were installed during the construction of the plant. At the time of the turbine efficiency tests these piezometers will be calibrated and a meter ultimately will be installed to integrate as well as indicate the discharge through the turbines. It is proposed to have a meter on each unit. A totalizing meter will be installed in the control room to indicate the total discharge through the plant.

Methods of testing hydroelectric units commonly used in this country have been found inadequate on most low head developments where large quantities of water are to be measured, because of the shortness of the approach passages to the unit. In Europe, current meters have been used for many years in making efficiency tests, and have been found particularly well adapted for use on low head developments. Several turbine efficiency tests have been made in this country with current meters, but on such tests only a few meters were employed; the results usually have been of doubtful accuracy. It was decided at Safe Harbor to follow the European method of making current meter tests and to employ the Ott meter so generally used abroad.

One difficulty encountered in making current meter measurements is the time required to traverse the area of the metering section properly. It was found that a great many metering points would be necessary for each horizontal traverse. Therefore 27 current meters of the spoked-wheel type were purchased; these were mounted in the same horizontal plane on a rack made of stream line rods. This rack can be lowered in the gate slots to any desired elevation for obtaining a vertical traverse.

It was recognized that the Ott spoked-wheel current meter consistently under-registers for angular flow. The metering section at the gate slots is just at the end of the bell-mouth so that there obviously would be considerable angular flow near the top of the metering section. To obtain accurate measurements in that area, 27 conical screw propeller current meters were purchased and mounted on the same current meter rack 6 ft above the spoked-wheel meters. It was found that the difference between the indicated velocities of these 2 types of meters increased uniformly with an increase in the angle of flow; thus for a given difference in observed velocity on the 2 types of meters the true angle of flow could be determined readily and a proper correction could be applied to obtain the true velocities passing the metering section.

## CONCLUSIONS

The test program conducted in coordination with the plant design has resulted in numerous improvements in operating performance, has effected savings in construction costs, and has permitted a more complete study of the behavior of the Safe Harbor units. Such a program eliminated to a large degree the necessity of relying too greatly upon the limited field experience available. No little part of the success of this program depended on the close cooperation of the engineers of the 2 turbine manufacturers who for the first time in hydroelectric development in America, jointly developed and manufactured turbines of identical design wherein practically all replaceable parts are interchangeable.

The first 6 months of actual performance indicates that the prediction of the cavitation limits for the turbines based upon the laboratory model test results are reasonably close, although a longer period will be necessary to establish *definitely* a close correlation between laboratory and field results.

# Vancouver Convention Upholds Coast Reputation

AS THE OCCASION of his first formal public appearance as president of the A.I.E.E., H. P. Charlesworth opened the 21st Pacific Coast convention of the Institute at the Hotel Vancouver, Vancouver, B. C., Tuesday morning, August 30, 1932.

Preceding Mr. Charlesworth was Mr. W. G. Murrin, president of the British Columbia Electric Railway Company, Ltd., who was introduced by the convention chairman, G. R. Wright. Mr. Murrin stressed the great value and importance to human welfare of the free and wide interchange of technical knowledge concerning the practical application of the fruits of scientific research, regardless of international or selfish boundaries. Of the 3 common media of such exchange—direct correspondence, the technical press, and the personal contacts and discussions possible only through conventions and technical meetings—the speaker urged increasingly serious attention to the latter.

In his brief response of appreciation for the official welcome, Mr. Charlesworth referred to the remarkably rapid advances that have been made in science and engineering expressing the belief that further progress is inevitable. Citing from the broad field of electrical engineering such examples as the modern facilities in transportation by land, sea, and air; in communication by wire and by radio; and in the applications of electric power devices that constantly are reducing the drudgery of factory, office, and home, the speaker pointed out that all of these must of necessity have a profound effect upon our daily life. In consequence, engineers, individually and collectively were pointed out as having in addition to obvious technical duties, a very real and human responsibility in sociological matters ranging all the way from local civic interest to national government.

A pleasant surprise to all, and a fitting tribute to the unremitting year-long efforts of the committees in charge, was the attendance of 300 persons. Every Section in the far-western Districts was represented as were also 13 out of the 14 Student Branches. In addition to President Charlesworth, Institute officers present included vice-presidents A. W. Copley of San Francisco, Calif., C. R. Higson of Salt Lake City, Utah, and L. B. Chubbuck of Hamilton, Ont., Canada. The attendance is analyzed in an accompanying tabulation.

Technical Sessions

The technical sessions featured the 14 papers listed on p. 519 of Electrical Engineering for July 1932, each paper drawing its share of discussion. They were divided among 4 sessions devoted in general to power generation; transportation, electrical machinery, and metering; station apparatus; and communication and power transmission. Presiding over these meetings, respectively, were A. W. Copley, H. V. Carpenter (past vice-president), L. B. Chubbuck, and C. R. Higson.

Table I—Analysis of Attendance at 1932 Pacific Coast Convention

| Classification | Location<br>Vancouver | <br>Dist. No. 9 | <br>Dist. No. 8 | <br>Misc. | Totals |
|---|---|---|---|---|---|
| Members | 66 | 41 | 21 | 7 | 135 |
| Men Guests | 59 | 4 | 2 | 1 | 66 |
| Women Guests | 28 | 16 | 12 | 3 | 59 |
| Students | 16 | 11 | 10 | 3 | 40 |
| Totals | 169 | 72 | 45 | 14 | 300 |

In addition to the foregoing, 2 student sessions were held, one with the gavel in the hand of F. C. Carmen, chairman of the University of Utah Branch, and the other under the direction of W. D. Hudgins, chairman of the University of California (Berkeley) Branch. At these sessions the following papers were presented:

Electrical Properties of Hardened Copper, A. J. Hill and Homer Lambkin, Montana State College.

Steam Versus Electric Drive for Sawmill Operation, E. A. Buckhorn, Oregon State College.

Electrical Reflections in A-C Machinery, D. J. Moore, University of Washington.

Comparison of Two Methods of Calculating a Transmission Line, Duane Olney and N. A. Miyota, Washington State College.

Effect of Atmospheric Conditions on Corona Loss, Victor Siegfried, Stanford University.

Short Circuit and Arcing Characteristics of Renewable Link Cartridge Fuses, Louis Beyha and Oliver Jesson, University of Southern California.

A Stroboscopic Device for Studying Rotary Motion, Kenneth Nielsen and W. S. Nishiyama, University of Utah.

Investigation and Application of the Ultra-Short Waves in Radio, J. H. Russell and J. A. O'Neil, University of Santa Clara.

The Parallel Type Inverter, Wilson McRae, University of British Columbia.

A Timing Instrument for Transients, Suitable for Measuring Time Lag of Spark-Over, Abe. Tilles, University of California.

The Design of an Efficient Amplifier Coupled to an Antenna, Sydney Sillitoe, University of Alberta. Read by H. Freedman, University of British Columbia.

Attendance at all technical sessions averaged by actual count well in excess of 100. The delegates and guests were invited to a special luncheon meeting of the Vancouver Electric Club to hear the address of Capt. E. A. Wheatley, registrar of the British Columbia Association of Professional Engineers, concerning the importance to engineers of their cooperating effectively in the control and application of engineering education.

Student Activities

In addition to the technical sessions already mentioned the Enrolled Students and their Counselors were the feature participants in a luncheon meeting held Tuesday, August 30, and a dinner at the University of British Columbia immediately preceding the annual student conference held there at 8 p.m., September 2, with Dr. J. H. Hamilton, counselor, University of Utah Branch, presiding. The meeting was opened by brief addresses by President H. P. Charlesworth and Vice-President A. W. Copley of the Pacific District, both of whom emphasized the importance of student activities in the further development of the Institute.

Of the 14 Branches in Districts 8, 9, and 10, eight were represented by their counselors and chairmen, and each of the others was represented by either the counselor or the chairman. Branch counselors present included: J. C. Clark, Univ. of Arizona; R. W. Sorensen, Calif. Inst. of Tech.; L. E. Reukema, Univ. of Calif.; N. C. Clark, Univ. of So. Calif.; J. H. Johnson, Univ. of Idaho; J. A. Thaler, Montana State Col.; E. C. Starr, Oregon State Col.; J. H. Hamilton, Univ. of Utah; O. E. Osburn, State Col. of Wash.; G. R. Shuck, Univ. of Wash.; and E. G. Cullwick, Univ. of British Columbia.

The Branch chairmen present included: Bruce Watkins, Univ. of Arizona; M. S. Hodge, Calif. Inst. of Tech.; W. D. Hudgins, Univ. of Calif.; J. H. Russell, Univ. of Santa Clara; R. R. Moore, Univ. of So. Calif.; G. W. Dunlap, Stanford Univ.; R. S. Stokan, Montana State Col.; R. J. Mather, Oregon State Col.; F. C. Carmen, Univ. of Utah; and P. W. Hand, State Col. of Wash.

Some of the topics of discussion were the desirability of the selection of the dates of future Pacific Coast conventions in order to secure Labor Day railroad rates, traveling expenses allowed for the conferences on student activities, and methods of providing for closer cooperation between the University of British Columbia Branch and the Branches in the North West District. The vice-presidents of the Pacific and North West Districts were requested to appoint a joint committee to consider these matters and prepare recommendations.

Much interest was exhibited in the student technical papers presented at the convention, and there was a discussion regarding the mimeographing, and advance distribution of the papers prepared for future conventions.

### Entertainment

The social program, delightful in its simplicity and satisfying in its variety, was opened formally by the reception for President Charlesworth, with a subsequent dance held Tuesday evening. Women's events included trips to various points of interest, an afternoon's outing in Vancouver's famous Stanly Park featured by tea and a pitch-and-putt golf tournament, and a bridge tea held Friday afternoon. Winners of golf prizes were Mrs. C. Arnott of Vancouver, B. C., and Mrs. H. O. Blair of Tacoma, Wash.; Mrs. H. V. Carpenter of Pullman, Wash., won a special prize for making a hole-in-one on her initial round.

A 4-hour boat trip with dinner served aboard drew 188 men and women out Wednesday evening in spite of rainy weather. The trip was made on the Canadian Pacific steamer "Princess Norah." The convention dinner held Thursday evening also proved to be an attractive affair, there being some 240 persons in attendance. President Charlesworth in addressing the banqueters briefly recalled one of the principal motives of the Institute as being "the advancement of the theory and practise of electrical engineering and its allied arts and sciences, the maintenance of a high professional standing among its members, and the development of the individual engineer." In this connection he emphasized how well the Institute's conventions in general and the Vancouver convention in particular functioned to maintain this underlying principle of development regardless of political boundaries. In part he said: "We are indeed advancing effectively the theory and practise of electrical engineering through the interchange of information . . .; also we are aiding the professional standing and development of our individual engineers. . . . Not only professionally but also personally do we gain from these meetings."

Concerning the much talked of matter of the engineer's place in our general social-economic structure, Mr. Charlesworth said in part: " . . . . Whether we are concerned with research, engineering, education, or any other branch of the profession, it is evident . . . . that we cannot but be called upon to play an even greater part in the problems attendant upon the application of the results of our work, and, in fact, in the general affairs of society. If we recognize these opportunities, and individually and collectively do our full share, and if we fully appreciate that we cannot approach these problems alone as engineers, but rather collectively with all other groups of society, we shall not only make a real contribution to the solution of some of the difficult problems now confronting our individual countries and the world in general, but we shall have enhanced materially the prestige of our profession."

Following Mr. Charlesworth's address the amateur dramatic club of the British Columbia Electric Railway Company cleverly enacted a little skit entitled "The Mayor and the Manicure." Prizes for Institute papers as announced on p. 418 of Electrical Engineering for June 1932, were presented by President Charlesworth; the presentation of golf prizes brought the evening's affair to a close.

Other activities for men included sight-seeing and several splendid inspection trips, the most popular one being the trip to the new Ruskin hydroelectric plant of the British Columbia Power Corporation. The annual golf tournament drew 54 registrants from among the golfers and the near-golfers. With the play at the Shaughnessy Heights Golf Club the aspirants were treated to a course not especially sporty, but replete with long holes and strategically located traps in great profusion. The Fisken Cup, prized Pacific Coast trophy named for John B. Fisken of Spokane, Wash., was won by J. E. Underhill (A'29) of Vancouver, B. C., score: 98 − 30 = 68 net. Mr. Underhill stated that he was as astonished as were his competitors; he never before had broken 100. Other winners were: Prof. E. G. Cullwick (A'26), G. K. Haspal (M'31), J. A. Tames (A'27), and S. Anderson of Vancouver; G. I. Wright (M'28) of Philadelphia, Pa., low gross (88); C. R. Higson (M'32) and Prof. J. H. Hamilton (A'28) of

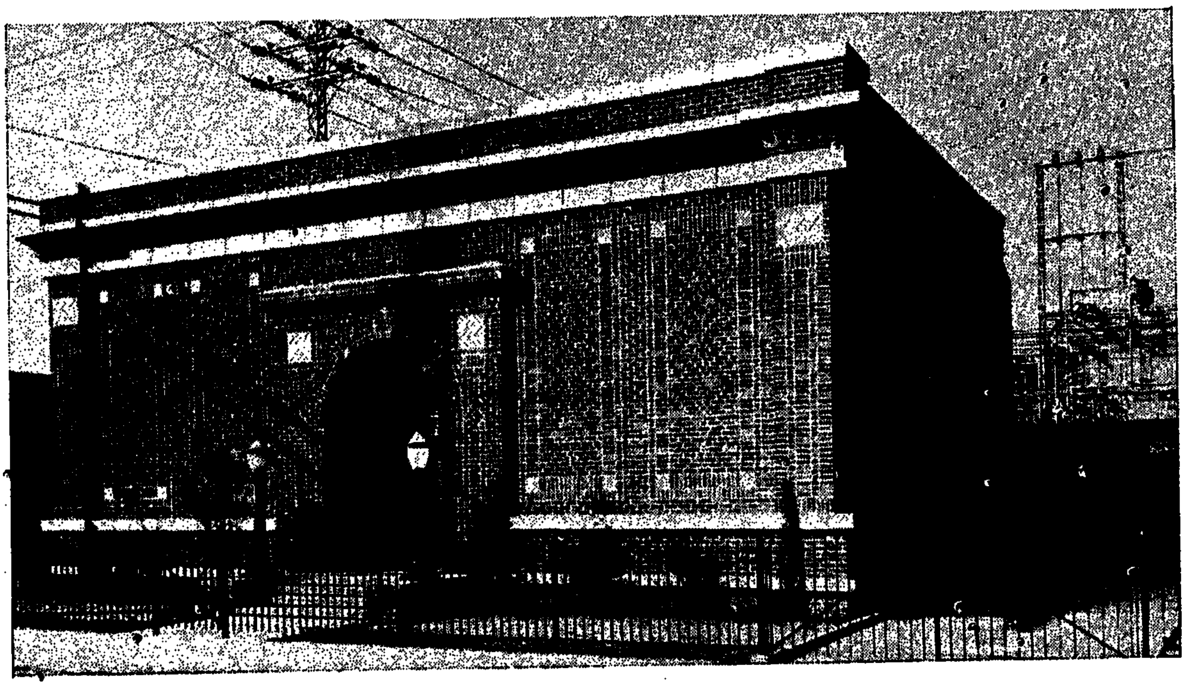
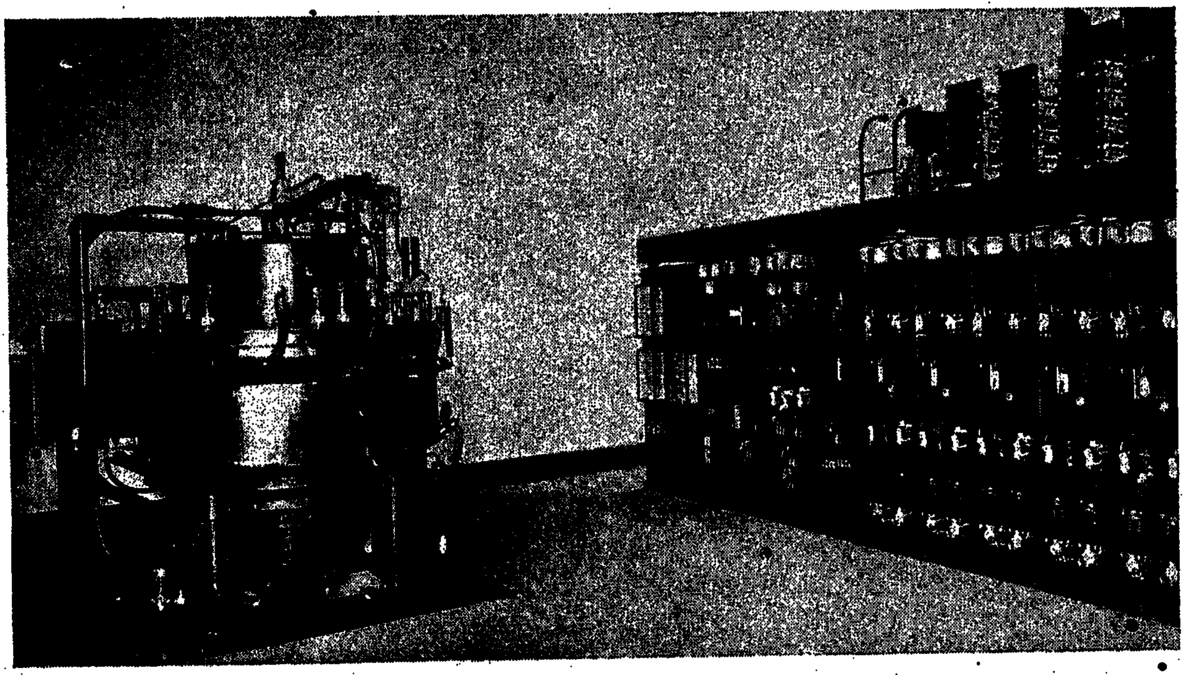
# Mercury Arc Rectifier Substation of Pleasing Design





Two additional mercury arc rectifiers, each of 1,500-kw. capacity, have been placed in service by the Los Angeles Railway Corporation in its new Slauson substation. The rectifiers are provided with complete automatic control. Both the exterior and interior designs of this substation are deserving of attention. Architectural features to harmonize well with other buildings in a residential district are incorporated in the building. One continuous switchboard provides the control for the 2 General Electric rectifiers, 4 a-c 16,500-volt incoming lines, 4 a-c tie breakers, 4 power transformers each rated 1,500 kva 16,500–935 volts, and 12 d-c feeders each rated 600 volts, 1,200 amp. This control board is particularly interesting in that it provides automatic, supervisory, and manual control—whichever may be desired.

Salt Lake City, Utah; J. I. Little (A'22), Prince Rupert, B. C. (158). Successful in estimating themselves into the kickers hat and lucky in having their names drawn therefrom were Joseph Hellenthal (M'23) of Seattle, Wash.; C. F. Norburg (A'28) of Spokane, Wash., and M. Legge of North Vancouver, B. C.

## District Meeting at Baltimore Impends

Shortly after this issue of Electrical Engineering goes to press the Institute's Middle Eastern District meeting will be held in Baltimore, Md., October 10–13, 1932, with headquarters in the Lord Baltimore Hotel. A report of this meeting is scheduled for the November issue, and a summary of the discussions on the Baltimore meeting papers will be presented as soon as they are made available by the discussers. To be considered for publication discussions should be written and mailed to the A.I.E.E., editorial department, 33 West 39th Street, New York, N. Y., on or before October 28, 1932.

The program of the Baltimore District meeting was announced in Electrical Engineering for September 1932, p. 663–4, and abstracts of all papers then scheduled for presentation at the meeting were also given in the September issue, p. 659–62.

## Institute Affairs Discussed at Vancouver Convention

A luncheon of Institute, District, and Section executives, and Student Counselors, was held in the Italian room of the Hotel Vancouver on August 31, 1932, in connection with the Institute's recent Pacific Coast convention at Vancouver, B. C. C. R. Higson (vice-president District 9) acted as chairman of the meeting, and after congratulating the local convention committee on their arrangements for this convention, briefly discussed the 1934 Pacific Coast convention. He called attention to the fact that the board of directors of the Institute had approved the recommendation made during the 1931 convention that the 1933 convention be held at Salt Lake City, Utah. The local members under the leadership of B. C. J. Wheatlake have begun their plans for the convention.

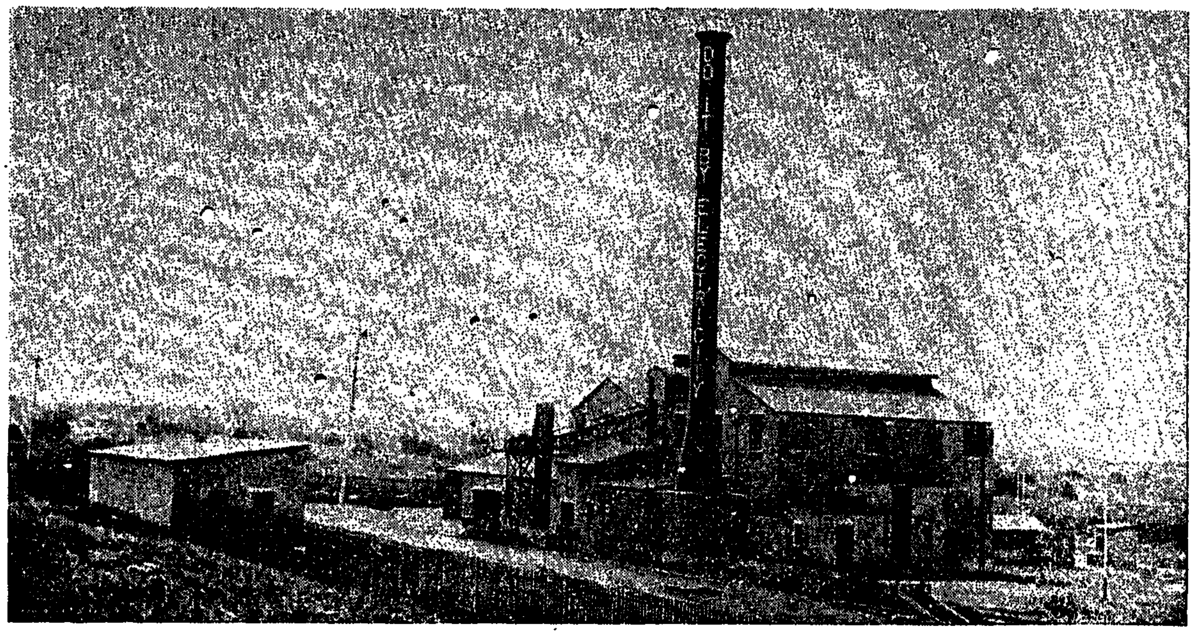
A. W. Copley (vice-president District 8) San Francisco, Calif., stated that the board of directors will decide in January 1933, the location of the 1934 Pacific Coast convention, and moved that this meeting recommend to the directors that the 1934 convention be held under the auspices of the Los Angeles Section. This motion was carried unanimously.

Pres. H. P. Charlesworth offered his congratulations to those responsible for the technical and student sessions and the entertainment features, commenting specifically on the featuring of student activities. He also said that Dr. Frank B. Jewett (past-president) had reminded him that the German electrical engineers this year are celebrating the sixtieth birthday of Dr. Carl Von Siemens, and had suggested that the convention send a congratulatory cablegram to Doctor Siemens. It was moved, seconded, and unanimously carried that H. H. Henline, acting national secretary, be requested to send this cablegram.

The publication in Electrical Engineering of papers not published in the Transactions was discussed, and a motion was carried that Electrical Engineering be requested to publish the paper "Metering of Symmetrical Components" by G. R. Shuck, which the technical program committee had recommended be not published by the Institute.

After further discussion of the value of Student sessions and the recommendation that close cooperation between Student Branches and Sections is highly desirable, the meeting adjourned.

## A Power Plant in Central Africa



A MODERN power plant differing considerably from those found in the United States is illustrated above. It is owned by the Ndola Electricity Undertaking, Ndola, Northern Rhodesia, Africa, and is located in the heart of the Northern Rhodesian copper belt. The photograph was supplied by D. W. V. Ellis (M'32), manager and engineer, Ndola Electricity & Water Undertakings.

## Nomination of 1933 Institute Officers

Actions specified in the Institute's constitution and bylaws relative to the organization of a national nominating committee are being taken, and the meeting of the national nominating committee for the nomination of officers to be voted upon at the election in the Spring of 1933 will be held between November 15 and December 15, 1932. All suggestions for the consideration of the national nominating committee must be received by the secretary of the committee at Institute headquarters, New York, N. Y., not later than November 15, 1932.

The sections of the constitution and bylaws governing these matters are quoted below:

**Constitution**

28. There shall be constituted each year a national nominating committee consisting of one representative of each geographical district, elected by its executive committee, and other members chosen by and from the board of directors not exceeding in number the number of geographical districts; all to be selected when and as provided in the bylaws; the national secretary of the Institute shall be the secretary of the national nominating committee, without voting power.

29. The executive committee of each geographical district shall act as a nominating committee of the candidate for election as vice-president of that district, or for filling a vacancy in such office for an unexpired term, whenever a vacancy occurs.

30. The national nominating committee shall receive such suggestions and proposals as any member or group of members may desire to offer, such suggestions being sent to the secretary of the committee.

The national nominating committee shall name on or before December 15 of each year, one or more candidates for president, national treasurer, and the proper number of directors and shall include in its ticket such candidates for vice-presidents as have been named by the nominating committees of the respective geographical districts, if received by the national nominating committee when and as provided in the bylaws; otherwise the national nominating committee shall nominate one or more candidates for vice-president(s) from the district(s) concerned.

**Bylaws**

Sec. 22. During September of each year, the secretary of the national nominating committee shall notify the chairman of the executive committee of each geographical district that by November 1 of that year the executive committee of each district must select a member of that district to serve as a member of the national nominating committee and shall, by November 1, notify the secretary of the national nominating committee of the name of the member selected.

During September of each year, the secretary of the national nominating committee shall notify the chairman of the executive committee of each geographical district in which there is or will be during the year a vacancy in the office of vice-president, that by November 15 of that year a nomination for a vice-president from that district, made by the district executive committee, must be in the hands of the secretary of the national nominating committee.

Between October 1 and November 15 of each year, the board of directors shall choose 5 of its members to serve on the national nominating committee and shall notify the secretary of that committee of the names so selected, and shall also notify the 5 members selected.

The secretary of the national nominating committee shall give the 15 members so selected not less than 10 days' notice of the first meeting of the committee, which shall be held not later than December 15. At this meeting, the committee shall elect a chairman and shall proceed to make up a ticket of nominees for the offices to be filled at the next election. All suggestions to be considered by the national nominating committee must be received by the secretary of the committee by November 15. The nominations as made by the national nominating committee shall be published in the January issue of ELECTRICAL ENGINEERING, or otherwise mailed to the Institute membership during the month of January.

(*Signed*) H. H. HENLINE,
October 1, 1932. *Acting National Secretary*

---

# Summarized Review of Some Pacific Coast Convention Discussions

PRINCIPAL discussions of the Pacific Coast convention papers are summarized herewith. The papers to which these discussions refer were abstracted in ELECTRICAL ENGINEERING for August 1932, p. 583–6.

Only discussion submitted in writing in accordance with governing A.I.E.E. rules is summarized. Complete discussion, together with all approved papers, will be published in the TRANSACTIONS.

### READING COMPANY'S PHILADELPHIA SUBURBAN ELECTRIFICATION

A. J. Schoch (Philadelphia, Pa.) discussed this subject and corroborated the attainments brought out in the paper as a result of electrification. He called attention to the simplicity and ease of erection and maintenance of the 2-wire catenary system which experience has shown results in a quality of current collection better than that obtained from the usual compound catenary systems. He referred also to the improvements made in the car equipment. Aluminum alloys were used in the non-stress carrying members, and by a careful location and arrangement of equipment underneath the car, the original installation was not only simplified but the job of inspecting and maintaining the equipment was made much easier.

### ELECTRICAL OPERATION ON THE GREAT NORTHERN RAILWAY

W. F. Coors (Tacoma, Wash.) discussed in connection with this subject several troubles encountered on the electrical equipment of the Milwaukee Road which were due to unexpected moisture conditions affecting insulation. One of these troubles occurred when under certain weather conditions the depression in the top of the traction motor frame housings for recessing the field pole capscrew heads filled with snow. Later when the traction motors warmed up at work, the snow would melt and the resulting water ran through the bolt holes into the traction motor cases, usually causing field coil insulation failures. This trouble was prevented by filling the recesses with battery sealing compound.

G. H. Walker (Seattle, Wash.) briefly but interestingly outlined the electric system of this electrification and the terms for purchasing power which include an increase in the demand charge when 13,000 kw is exceeded. It is of interest to note the method by which this demand is limited. This was accomplished by equipping each locomotive unit with an indicating ammeter visible to the engineman and connected in the circuit to the synchronous motor of the motor generator set. Tests were conducted to determine the demand for various readings on the ammeter for each type of locomotive unit. The results were tabulated and given to the train dispatchers who in turn when dispatching trains assign a load limit to each locomotive unit on the line for any given period of time. This the dispatcher does by giving orders to the engineman not to exceed so many amperes between certain locations or at certain times. This method of power limitation has been used without undue handicap to schedules and it has resulted in a considerable saving in power costs. The discussion was supplemented with data on power consumption and traffic, together with a reproduction of an actual train sheet and load diagram.

Another discussion on this subject by R. T. Strong (Seattle, Wash.) drew attention to the distinction that must be made between the terms "locomotive unit" and "locomotive." The latter term designates one or more locomotive units operating together. Mr. Strong then illustrated the importance of selecting locomotive unit sizes so as to obtain the greatest flexibility combined with maximum standardization. It also was illustrated with data given in the paper and from the history of most railway electrifications that train weights originally specified by the railways rarely have been adhered to. The discusser believes that electrical engineers laying out a new railway electrification should keep this tendency in mind and leave an ample margin in the design for increases in train weight. In connection with the condensation difficulties described in the paper, Mr. Strong explained 2 additional causes contributing to high temperatures in the tunnel. These were the presence of warm springs within the tunnel and the heat thrown off by the chemical action of the setting of newly poured concrete. He believes that difficulties with the locomotives are due entirely to condensation within the cabs, and not to snow or water drawn in from the outside.

### CORONA LOSS MEASUREMENTS

In connection with this subject W. S. Peterson (Los Angeles, Calif.) presented and analyzed a theoretical formula modified by empirical correction to fill the need for some method of calculating corona loss for the lower values of losses as well as the higher values. In the development of the formula the corona loss was considered to be that due to charging current flowing radially through the corona envelope. The drop in voltage through the envelope was assumed as being the integral of the potential gradient from the point where the gradient in air exceeded 53.6 kv per in. effective values, to a point on the conductor at some higher value. Instantaneous values of current and voltage were used, and for the portions of the cycle at which the voltage is too low to cause air breakdown, no loss was assumed to occur. The discusser explained that the formula evolved from this theory and further empirical corrections had served quite well to give accurate curves for practical engineering purposes. Excellent agreement also has been obtained with a great variety of tests.

### TRIPLE HARMONIC EQUIVALENT CIRCUIT IN 3-PHASE POWER TRANSFORMER BANKS

P. W. Blye (New York, N. Y.) in discussion of this subject cited his experience with tests on transformers similar to those made by the authors. These tests corroborated their general conclusion that at a given excitation or over a narrow range of excitation, the equivalent $T$ network described in the paper presents a simple and accurate method of dealing with triple harmonics arising in 2-winding transformers. However, the discusser did not agree with several points brought out in the paper incidental to the general conclusions. For example, the statement in the paper that the total leakage impedance as measured by the usual short-circuit method was found to be considerably in error as compared to the sum of the individual leakage impedances used in the equivalent circuit and observed at normal excitation by the delta-opened-delta method. He also recalled certain cases where the leakage impedance associated with one winding of a 2-winding transformer actually had been found to increase slightly with increasing excitation.

A. Boyajian (Pittsfield, Mass.) in his discussion of this subject referred to the application of a single equivalent circuit for bank No. 3 in Fig. 6 of the paper. He explained that this circuit was not applicable both for the currents produced by $E_3$ and for those produced by $E_2$. He believed that a single equivalent circuit to satisfy these conditions would have to be of the 6-link type which is very difficult to construct and use. It was felt that the good results claimed by the authors with the use of a single 3-link equivalent circuit seemed to imply that in the case under consideration the 2 equivalent circuits did not happen to differ materially from one another.

Another discussion by H. V. Carpenter (Pullman, Wash.) considered the magnetic conditions existing during the tests; it was explained that if 3 single-phase transformers were used, each phase would have its own independent magnetic core; if one type of

3-phase transformer were used, the 3 flux paths would be partially but not wholly independent; while if the other type were used, any flux passing through one core must return through the other 2. In this latter case the third harmonic flux would find no return path; so it would seem likely that the 3 different conditions would give somewhat different results.

D. I. Cone (San Francisco, Cal.) discussed this subject and it is his belief that despite the number of published articles, there still is need for the presentation of methods for quantitative prediction of the behavior of given networks. He believed this paper is a helpful contribution toward filling that need. In reference to Fig. 16 he felt that it was most encouraging to observe that even at the resonance point, it was practicable to predict the approximate magnitude of the third harmonic current. In conclusion, he suggested as a desirable extension of this study, others that would concern the distribution of triple harmonics in 3-winding transformers and associated lines.

E. G. Cullwick (Vancouver, B. C.) in his discussion of this paper questioned the authors' statement that the harmonics in the exciting current of a transformer are produced by voltages of like frequency produced in the transformer itself, due to the action of the steel core. He explained that due to the varying reluctance of the iron core, the magnetizing current necessary to produce the flux would not be sinusoidal, but would contain strong third and higher odd harmonics. To represent these harmonics in an equivalent circuit, it is logical to replace the varying impedance of the transformer by a constant impedance and a generator of odd harmonics, but the discusser did not believe it was accurate to state that the harmonics were actually due to electromotive forces generated in the transformer windings.

### SEGREGATION OF HYDROELECTRIC POWER COSTS

J. S. Moulton (San Francisco, Cal.) discussed this subject in regard to the conclusions in the paper that assuming that a plant could be constructed to operate at 100 per cent load factor, the base cost per kilowatthour would be the energy cost of service, and that the additional cost incurred by reason of less than 100 per cent load factor operation would be the demand cost of service. The discusser felt that the first of these conclusions was in reality a premise upon which the validity of much of the balance of the paper depended. He pointed out that it is equally correct to assume that the costs involved can be expressed upon a per kilowatt basis. The desirability of considering base costs as demand costs of service rather than an energy cost of service is illustrated by Fig. 7 of the paper and shows that with a fixed generating capacity installed, if the average kilowatts fall below 100 per cent load factor, the cost per kilowatthour increases. From a rate making standpoint, if the output of such a plant is sold upon a kilowatthour basis and upon the assumption that the plant will operate at 100 per cent load factor, and conditions change so that it operates at less than this load factor, it is obvious that at the fixed price per kilowatthour the total plant costs will not be met. On the other hand if the capacity is sold upon a kilowatt basis, then the total plant costs will continue to be met regardless of how the load factor may vary.

### FACTORY ASSEMBLIES FOR SUBSTATION DESIGN

J. S. Moulton (San Francisco, Cal.) discussed this subject also and reported that the average life of transmission switchboards in place on a certain system was 14.4 years. The average life for distribution switchboards was 13.2 years. The transmission switchboard account included high voltage oil circuit breakers, disconnecting switches, switch structures and miscellaneous appurtenant equipment. The distribution account included oil circuit breakers of an operating voltage of 11 kv or below, and otherwise was similar to the transmission account. As most of the equipment was relocated and some of it was moved several times during its life, the discusser suggested that serious study should be given to ways of increasing the capacity of existing apparatus so as to eliminate relocation if not abandonment. Study also should be given to ways of reducing the amount of installation labor, which must be written off in the case of a change in location.

## Section Activities for Fiscal Year Summarized

As part of an effort to distribute as widely as possible the benefits of affiliation with the Institute, a plan was formulated in 1902 to organize local groups of Institute members in electrical centers. Since that time the activities of these Sections have expanded very rapidly, and with the formation of a Montana Section authorized by the Institute's board of directors on June 24, 1931, the number of Sections was brought up to 60. Approximately 80 per cent of all Institute members now are within Section territory.

Section activities for the fiscal year ending April 30, 1932, were normal, and programs included a wide variety of interesting and important subjects. Despite the unfavorable business conditions, the number of applications for admission received from Section territories during the fiscal year was more than 94 per cent of the corresponding number for the preceding fiscal year (1,209 and 1,280, respectively). Many of the Sections have appointed committees to study the qualifications of their members and to urge those who are fully qualified for a higher grade to submit their applications for transfer.

**Table I—Section Meetings Held During Year Ending April 30, 1932**

| | A.I.E.E. Members | | Meetings During Year | | |
|---|---|---|---|---|---|
| Section | Aug. 1930 | Aug. 1931 | No. | Avg. Attendance | Avg. Attendance as Per Cent of Membership Aug. 1931 |

| Total......60 | 14,596 | 14,410 | | | |

Total number of meetings........ 497
Total attendance............... 105,325
*Organized September 12, 1931.

Arrangements made in recent years involving interesting developments in activities were continued in effect. Notable among these are: the 2 joint meetings of the Pittsfield and Schenectady Sections each year for the presentation of papers by younger members in competition for prizes; the practise of Sections to have programs supplied largely by their members; the effective public speaking instruction sponsored by the New York Section; special joint meetings with students in several Sections; the lecture courses sponsored by the Chicago Section; and local prize competitions held by many Sections. The

Cleveland Section distributed with the notice of its December meeting a questionnaire designed to learn in considerable detail the wishes of its members with respect to the types of meetings to be held in the future. The suggestions received are expected to be of material aid in the planning of meetings for this coming year.

The group (power, transportation, communication, illumination) activities of the Chicago and New York Sections were continued with excellent results. The Chicago Section and other local engineering organizations continued the arrangements for post-college education of engineers as begun in 1929. A review of these activities was published on p. 280–1 of the April 1932 issue of ELECTRICAL ENGINEERING.

Resolutions were adopted by the board of directors October 23, 1931, urging the Sections to consider organizing engineers' unemployment relief committees in cooperation with other engineering groups. A large number of the Sections participated in the formulation and execution of plans directed toward making work and furnishing financial assistance to engineers in need for whom positions could not be secured. A review of these efforts and their results is contemplated for an early issue of ELECTRICAL ENGINEERING.

In the fifth annual report on Section and Branch activities covering the fiscal year ending April 30, 1932, considerable information concerning meetings is given. This information is presented herewith in Tables I and II.

**Table II—Section Meetings Held During Last 3 Fiscal Years**

| | Fiscal Year Ending April 30 | | |

| Average number of meetings | 8.6 | 8.3 | 8.3 |
| Total attendance | 84,727 | 108,523 | 105,325 |
| Avg. attendance per meeting | 177 | 221 | 212 |

## Branch Activities for Fiscal Year Summarized

The interest in the Student Branch activities which has been so marked for the last 2 or 3 years is still as alive as ever, as evidenced by the number of meetings held and the large number of student papers delivered. There is no doubt that this form of activity of the Student Branches, if continued, is destined to produce electrical engineers who can write good technical papers and present them clearly and effectively.

The committee on Student Branches, in addition to giving electrical engineering students training in the activities of the Institute while they are still in college, has been working for the past year on the problem of improving the grade of the student who applies for courses in electrical engineering in the educational institutions. For the purpose of encouraging those who should go into electrical engineering, and to discourage those who are unfitted for such a career, the committee prepared a 32-page booklet. Following a preliminary distribution of this booklet, requests for about 9,000 additional copies were received.

**Table I—Branch Meetings Held During Year Ending April 30, 1932**

**Table III—Summary of Monthly Reports on Branch Activities Appearing in the November to June Issues, Inclusive, of ELECTRICAL ENGINEERING of the Last 5 Academic Years**

| | 1927–28 | 1928–29 | 1929–30 | 1930–31 | 1931–32 |
|---|---|---|---|---|---|
| No. of Branches Jan. 1 | 95 | 100 | 104 | 107 | 109 |
| Avg. no. of Branches reporting meetings per month | 58 | 56 | 60 | 67 | 68 |
| Avg. no. of Branches reporting student talks per month | 24 | 30 | 35 | 39 | 36 |
| Total no. of meetings | 807 | 806 | 891 | 957 | 956 |
| Total no. of student talks | 646 | 767 | 893 | 966 | 919 |

The committee on Student Branches also has contributed the chapter on electrical engineering for the pamphlet being prepared by The Engineering Foundation to contain information on the main divisions of engineering.

In Tables I to VI, inclusive, is given information which was presented in the annual report on Section and Branch activities, covering the fiscal year ended April 30, 1932.

### Table IV—Camparison of Branch Activities by Districts

| District | No. of Branches Jan. 1 | Avg. No. Meetings per Branch | Avg. Attendance per Meeting | Approx. Avg. No. Student Talks per Branches | No. of Branches Reporting 8 or More Student Talks |
|---|---|---|---|---|---|
| 1 | 13 | 9.5 | 42.5 | 8.7 | 4 |
| 2 | 18 | 8.3 | 51.3 | 10.7 | 5 |
| 3 | 8 | 10.3 | 37.8 | 7.3 | 4 |
| 4 | 17 | 9.8 | 47.0 | 12.3 | 6 |
| 5 | 16 | 10.5 | 75.0 | 6.9 | 3 |
| 6 | 9 | 10.7 | 32.5 | 5.9 | 4 |
| 7 | 14 | 10.9 | 42.0 | 10.7 | 8 |
| 8 | 7 | 14.3 | 31.5 | 4.7 | 2 |
| 9 | 6 | 13.5 | 58.1 | 21.5 | 3 |
| 10 | 1 | 11.0 | 24.3 | 17.0 | 1 |

### Table V—Conferences on Student Activities

| District | Location | Date |
|---|---|---|
| 1 | Rochester, N. Y. (North Eastern Dist. Mtg.) | 5/ 1/31 |
| 8 & 9 | Lake Tahoe, Calif. (Pacific Coast Conv.) | 8/27/31 |
| 7 | Kansas City, Mo. (South West Dist. Mtg.) | 10/23/31 |
| 4 | Gainesville, Fla. | 12/ 4/31 |
| 2 | Haverford College, Pa. | 3/14/32 |
| 5 | Milwaukee, Wis. (Great Lakes Dist. Mtg.) | 3/14/32 |
| 6 | University of Denver | 4/15–16/32 |

### Table VI—Student Conventions

| Sponsored by District | Location | Date | No. of Student Papers |
|---|---|---|---|
| 1 | Rochester, N. Y. (North Eastern Dist. Mtg.) | 5/1/31 | 8 |
| 8 & 9 | Lake Tahoe, Calif. (Pacific Coast Conv.) | 8/26/31 | 12 |
| 7 | Kansas City, Mo. (South West Dist. Mtg.) | 10/23/31 | 10 |
| 4 | Gainesville, Fla. | 12/4/31 | |
| Phila. and Lehigh Valley Sections | Haverford College | 3/14/32 | 4 |
| 5 | Milwaukee, Wis. (Great Lakes Dist. Mtg.) | 3/14/32 | 10 |
| 3 (and New York Section) | New York | 4/29/32 | 3 |

# Pearl Street Station Opened 50 Years Ago

September 4, 1932, marked the 50th anniversary of Thomas A. Edison's first permanent commercial incandescent lighting system. This first Edison system was the Pearl Street station and district in lower New York City.

The anniversary was celebrated by 2 events. The first, on September 4, was held at the site of the old station, 255–7 Pearl Street, at which many Edison veterans and men of prominence in the electric light and power industry were present. The second observance took the form of a dinner held on September 12, and was attended by representatives of the electrical industry and civic, scientific, and engineering bodies.

At its opening on September 4, 1882, the Pearl Street station served an area of about 1 sq mile in lower Manhattan, distribution being by about 15 miles of underground cable. The capacity of the station was approximately 750 hp, and supplied electric light to 59 customers.

**Trade Acceptances Urged for Financing.**—A concerted plan has been initiated by leading American industrialists to stimulate interest in the use of trade acceptances as a means for the expansion of the volume of credit available to industry. The use of trade acceptances has the effect of speeding up the turnover, increasing the net return, and improving the credit standing of business concerns, since collections would be expedited by the substitution of readily negotiable paper for slow open-book accounts. The trade acceptance method should be restricted to current transactions for purchases and sales of goods, and should not be extended to past due accounts. In order to give definite information concerning the trade acceptance method and to assist in determining the advisability of adopting this system in any particular business, circulars have been sent out by the National Industrial Conference Board, Inc., New York, N. Y., in which it has endeavored to set forth briefly the operations of the plan and the advantages to American industry which would result from its use.

# Section and Branch Joint Meetings Continue Successful

The cooperative relations between Institute Sections and neighboring Student Branches of the Institute have continued to receive much attention during the past year. The excellent methods developed for maintaining close contacts between Sections and Branches were continued, and the results are becoming increasingly apparent as more and more of the students who have participated in them subsequently have become active Section members.

Some of the principal cases of such cooperation during the past fiscal year and which resulted in obvious benefit both to members of the Sections and Branches, are given in the annual report on Section and Branch activities, covering the fiscal year ending April 30, 1932. This information is presented herewith in Tables I and II.

### Table I—Section or Joint Section and Branch Meetings With Active Student Participation

| Sections | Schools | Date | Student Talks | Attendance |
|---|---|---|---|---|
| No. Carolina | Univ. of No. Carolina | 11/10/31 | 1 | 115 |

| Total | | 13 | 51 | 1,014 |

* No Branch.

# Floodlighting Aids in Pushing Construction

ONE construction project of sufficient urgency to require 24-hr per day activity was the building of a 13,000,000-bushel grain elevator at the Port of Albany, N. Y. Night operations were facilitated by a floodlighting installation consisting of 2 wooden towers 60 ft high supporting 6 1,000-watt General Electric floodlights at each of 2 locations; these units were supplemented by 3 units located on the roof of a concrete mixing structure, making a total of 15 kw for the complete installation.

# Annual Economic Conference Held

The second annual economic conference for engineers was held at the engineering camp of the Stevens Institute of Technology, near Johnsonburg, N. J., August 27 to September 5, 1932. Attendance this year was particularly gratifying, and was distinguished by the presence of a number of individuals prominent in engineering and economic activities, as well as many others interested in acquiring a knowledge of the broader economic aspects of present day life. Perhaps the most important thing about the conference was the fact that it evidenced a considerable desire on the part of engineers to assist in understanding and solving the large scale problems of political economics, the creation of which problems engineering accomplishments are held at least partially responsible.

The morning lectures continued throughout the 10 days of the conference, and were divided into 2 sessions. One on the subject of "Money" was conducted by Prof. W. D. Ennis, head of the department of economics of engineering at Stevens Institute of Technology, and the other on the subject of "Banking" was conducted by A. V. Shaw, investment counsel, of New York, N. Y. The afternoons were left free for any activities desired, which included swimming in the spring-fed lake at the camp, and golf and tennis at other points in the vicinity. Evenings were devoted to a series of conferences on various subjects, each under the leadership of an authority in his particular field.

In addition to analyzing the existing economic system, definite suggestions were made at these conferences for remedying ills and assisting in the stabilization of prices and industrial activity. These suggestions might be grouped roughly into 2 classes, one of which is the modification of the existing system by measures under government control and for the purpose largely of regulating credit, and the other contemplating more radical alterations in the system. It is felt that those present at these conferences obtained a clearer idea of the more or less mysterious forces underlying economic changes, and were left with a definite desire to be of assistance in the solution of economic problems.

# Southern California Power Official Dies

Russell H. Ballard, president of the Southern California Edison Company, Ltd., died of pneumonia at his home in Los Angeles, Calif., August 24, 1932. Mr. Ballard was born in Hamilton, Ontario, Canada, July 26, 1875, and came to the United States in 1883, working as an office boy in the Thomson, Houston Electric Company in Chicago, Ill. He was with the treasury department of the General Electric Company, Schenectady, N. Y., from 1890 to 1893, and was placed in charge of collections and credits for this company in the southern states, with headquarters at Atlanta, Ga., in 1896.

Except for about 4 years between 1900 and 1904, Mr. Ballard has lived in Los Angeles since 1897, serving the Southern California Edison Company, Ltd., and its predecessors. Starting first as bookkeeper and later becoming auditor, Mr. Ballard progressed steadily through the company's organization, being appointed vice-president and general manager in 1924, and president in March 1928. His organizing and operating genius was recognized throughout the industry.

He was a past-president of the National Electric Light Association and the Pacific Coast Electrical Association, and held membership in the Franklin Institute of Philadelphia, Pa. He has been the recipient of many honors and was the first to receive the John B. Miller Medal for distinguished service to his own company. In recent years Mr. Ballard has been identified prominently with community work in Los Angeles.

G. C. Ward (M'24) its senior vice-president will direct the Edison company's activities "with the advice and counsel of the enlarged executive committee" according to an official announcement recently made which stated that any adjustment in the management that may become necessary by reason of Mr. Ballard's death will be deferred.

# "5-Watt" Lamps Which Average 12 Watts

Incandescent lamps may and do vary with respect to light output and efficiency—qualities not designated on the lamp. The public, however, should be able to rely upon the substantial correctness of the watts designation which does appear on the lamp.

Recently Japanese lamps have been found upon the American market bearing "5-watt" designations. Electrical Testing Laboratories, Inc., New York, N. Y., on behalf of member companies of the Association of Edison Illuminating Companies, having surveyed these products, find that such lamps are anything but 5 watts, averaging about 12 watts (as shown in Table I) and ranging as high as 20 watts. Such misleading marking of incandescent lamps is inexcusable, these laboratories contend.

**Table I—Measurements of Wattage of Japanese Lamps, Rated at 5 Watts, Purchased in Various Cities**

| City | Number Measured | Average Watts |
|---|---|---|
| Detroit | 23 | 11.2 |
| Warren | 10 | 10.6 |
| Boston | 53 | 11.1 |

—From an article appearing in *Electrical World* for August 20, 1932, p. 253.

**A New Series of Magnet Steels.**—The perfection of a new series of magnet steels by Dr. T. Mishima, an assistant professor at the Tokyo Imperial University of Tokyo, Japan, is announced in the July 1932 issue of *Ohm*, a Japanese magazine devoted to electrical engineering. A translation of the original announcement prepared by J. A. Rabbitt and Dr. T. Fujiwara of the Japan

Nickel Information Bureau, Tokyo, states that these new magnet steels are called by the inventor "MK" steel and are characterized by a very high order of permanence. The announcement says that the coercive force is claimed to be about 9 times that of the usual tungsten magnet steels and $2^1/_2$ times that of the best cobalt magnet steels. The residual magnetism can be varied so that its value is between that of tungsten and cobalt magnet steels. The MK steels consist mainly of iron, nickel, and aluminum. A typical composition is 25 per cent nickel, 10 per cent aluminum, and the balance iron, but the nickel may be varied from 10 to 40 per cent and the aluminum from 1 to 20 per cent. The MK steels are not readily forged and therefore must be cast into the desired form. However, their desirable magnetic properties are developed by simple annealing and they are therefore free from the difficulties of quenching which is required with the tungsten steels. In addition, the announcement says that the magnetic properties of the MK steels do not change appreciably with increase in temperature even to the extent of several hundred deg C. They are said also to be magnetically stable when subjected to mechanical vibration or shocks.

# Letters to the Editor

CONTRIBUTIONS to these columns are invited from Institute members and subscribers. They should be concise and may deal with technical papers, articles published in previous issues, or other subjects of some general interest and professional importance. ELECTRICAL ENGINEERING will endeavor to publish as many letters as possible, but of necessity reserves the right to publish them in whole or in part, or to reject them entirely.

STATEMENTS in these letters are expressly understood to be made by the writers; publication here in no wise constitutes endorsement or recognition by the American Institute of Electrical Engineers.

## Has Man Benefited by Engineering Progress?

*To the Editor:*

From the articles printed in ELECTRICAL ENGINEERING on the question, "Has Man Benefited by Engineering Progress?" and the letters of comment they have elicited, it is plain we engineers feel moved to a certain searching of our hearts to determine whether we are living up to what we conceive to be our proper position in the community; and with this there goes also a disposition to inquire whether, on the part of the community, there is a readiness to accord us all the recognition to which we feel entitled. It is our belief, more or less definitely formulated, that most public questions are, in their essence, engineering problems, whose solutions should be sought, therefore, by the methods of our profession; and we tend to receive with some impatience what we regard as the snap judgments on these of politicians, financiers, and real estate operators, judgments that appear to us to be derived rather from the inner consciousness of the presenter than from that careful collection of data and that correct treatment of them to which we are used. We are accustomed to think, and now and then to say, that the competence to pass on these questions lies really with us, rather than with any of the other professions or callings; and we are wondering whether, if this be not generally admitted, the fault lies with the other professions, possibly jealous of us, or with the community at large, apparently oblivious to us, or with ourselves, for hiding our light under a bushel. We are asking ourselves, now, what, if anything, we may, can, or must do to set these things right.

It is being said among us, we must emerge from any seclusion where we may have been keeping ourselves, we must assume a leading part in civic and national affairs. . . . The picture is painted of our profession as the center from which shall emanate influences to guide our cities, our country, toward ideals of spaciousness and beauty, and of our publications as the inspiration and comfort of all that are fighting the good fight against ignorance, indifference, or turpitude. . . . This, briefly, is the picture some of us see in our minds' eyes; what is wrong with it?

Perhaps nothing, but, at any rate, it will be wise to look over the field more in detail, before deciding to enter the competition. For it is a competition. So far are our public problems from going a begging for solution that the want for an answer to any question of social policy is as uncommon as Byron found that for heroes to be, "When every year and month send forth a new one." . . . We wonder, and, as has been hinted, we envy; and we ask, if a physician or a jurist can do these things, why may not an engineer do them better? Ah, why? It will not be safe to leave that question behind us unanswered.

There is a welcome emancipation for the mind in considering unfamiliar things. About these, untrammelled by stubborn facts, the fancy may play; since we do not know the truth about them, we may paint them to suit us; if we do not confess our ignorance, and speak oracularly, we may succeed in having our utterances accepted at their face value. We may even attain to believing them ourselves, and thus may our dreams be in a fair way to come true. So it happens that, if a silk stocking manufacturer has visited London or Paris recently, and is asked what, from his observation while abroad, he would offer as a relief for the congestion in Philadelphia's streets, he does not hesitate to give a comprehensive answer. . . . But, is this what we are yearning to emulate?

Certainly not! We know that easier way is not for us. It is not that we assume any unhuman superiority; we were men before we were engineers. We will bet on a horse with any justice of the supreme court; we are as ready as the next man to tell a friend how to cure his cold; but if you ask us what is the correct ratio of the height of a building on Chestnut Street, between 10th and 11th, to the width of that street, we will say we do not know; and we stir uneasily, if we hear a clergyman answering that question offhand. The trouble is, these questions, as we recognized at the outset, are engineering questions, and we are estopped from answering them as do those in other walks of life. Those others, at whose ready-made pronouncements we have been smiling, are just as chary as we of resolving doubts within the provinces of their professions; the physician does not diagnose the disease without seeing the patient, nor the lawyer take the case without knowing all the evidence. These engineering problems are ours to solve, and ours only, but we must solve them in our way, and that way is by the collection and study of data. The engineering profession cannot undertake, in the blithe, light-hearted way of those we have been belittling, to take the lead in these public projects.

Must we, then, redraw our picture, and shape it farther from our heart's desire? Let us look over the field again. How fare these competitors of ours in the long run; do they finish the race? Seldom, if ever; we are justified in our reluctance to take them seriously. Their dreams, lacking both inspiration and perspiration, prove evanescent. Our rulers, the professional politicians, regard them with the tolerant contempt the professional has always for the amateur; that is the measure of their futility. If then, we might enter the field in our own way, handling technical questions as technicians, we should encounter no opposition. Is that a practicable course?

It would hardly seem so, for the conclusive reason that we are not given, and cannot take, the opportunity for the collection of the essential data on most of these questions. . . we can easily see they often involve such sciences as psychology, economics, and sociology, all sciences that have great difficulty with the question, "How much?" when asked of their subject matter. Such sciences give the engineer nothing to take hold of. There may be such a technique as human engineering, or social engineering; and all engineers must include economic factors in their problems; but how far we are from effectually applying such sciences, in the true engineering sense, is quite clear from a reading of the series of articles that instigated this inquiry. Quite as able they are as anything from the bankers, the captains of industry, the statesmen, the educators; but it seems they should be taken as a salve, rather than as an excitant, for our itch to get our hands on the wheel of the ship of state. We are not yet ready, no readier than those we condemn.

Obviously then, a course of preparation is indicated. Just what form that should take is the first question to which we should address ourselves. A central bureau for the collection of data seems the first requisite. A closer union among all our national engineering organizations is another. It is the voice of the engineers of America, and not that of the electrical engineers alone, that should be heard on national questions. An ample headquarters and close communication with our outposts, we already have. Let us now bend our energies toward perfecting the preparation we need, deferring, until that is in operation, all further complaints of not being permitted the opportunities we feel we can seize when we are prepared.

Very truly yours,

RUDOLPH H. KLAUDER (A'97)
(7447 Devon St., Mt. Airy,
Philadelphia, Pa.)

---

*To the Editor:*

A word of caution should be raised in the discussion about the mechanization of man's activities and about the assured deleterious influence of the increasing tendency of mankind to remain indoors.

The chocolate-brown skin of the beach habitue is a striking example of what the human body will do in order to protect itself from an overdose of the sun's radiation. Melanin is laid down in the skin to lessen the penetration of the light. Perfect health can be had with an infinitesimal amount of the solar radiation which an individual who lives out-of-doors absorbs.

The effect of drugs, of exposure to light, and of other stimuli follow well-known physiological laws which have more or less of a logarithmic character because of which a little goes a long way. Fish live out of range of the therapeutic effect of the sun's rays, and birds and the beasts of the forest and field are covered with scales, feathers, hair, wool and what not that most effectively keep the sun's rays away from nearly all of their skin. So it is evident that the skin need not be exposed to very much light.

A modern residence, be it a palace or overcrowded tenement house, possesses many and distinct advantages over the cool, damp, sweaty-walled cave without, for example, any semblance of toilet facilities.

Our getting into clothes has been gradual. Hundreds of generations of Caucasians, at least, have passed into and out of this earth since we first began to dress. Yet it would seem that the population of the earth is greater now than in any previous era. This is a pretty good indication that our present mode of life is as healthful as it has ever been.

The medical examinations of candidates for military service during the World War showed a greater percentage of physical defects among those from the rural districts than among those from the urban population in spite of the fact that the former were leading an outdoor life.

These conditions are greatly at variance with Bachem's quotation from Pearl, "Mortality is distinctly lower for outdoor than for indoor workers. This indicates the superior healthfulness of outdoor life." (See twelfth article of Engineering Foundation's symposium "Has Man Benefited by Engineering Progress?" in Electrical Engineering for August 1932, p. 553–5.) It is a typical illustration of how biometrical data and observation can be interpreted to illustrate a particular tenet. Those who work outdoors invariably have more diversified tasks to perform and require a greater all-round exercise of mind and muscular coordination and, undoubtedly, for this important reason are also more inclined to be healthy.

The machine has been mankind's greatest boon and has given an unparalleled impetus to civilization. The great problem, with the enormous saving of time and effort thus effected, is not to urge mankind to seek pleasure on the picnic grounds or in the public amusement halls where paid performers entertain but to urge it to use gainfully the surplus energy which it now has as a result of mechanization. The mere seeking of pleasure and taking of recreation leave a less beneficial permanent trace of the satisfaction afforded than do more worthwhile things.

A people who are imbued with the spirit of ambition and are willing to sacrifice for education and advancement in the arts and sciences and even in commerce and industry will profit through a raising of the general level of desire above the base spirit of pleasure seeking, which, at least in part, now prevails. Very wisely the founders of our country put the pursuit of happiness after life and liberty, thereby, tacitly perhaps, recognizing that its consideration should not come first.

There should be fewer pool rooms and motion picture theatres and more schools, churches, and privately owned homes. Pleasure seeking in itself is invariably not so conducive to true happiness as is creative achievement.

Very truly yours,
Roy Kegerreis, M.D.

## Engineering Subjects in the College Program

*To the Editor:*

The measure of success achieved by the technical schools in training students depends largely upon the ability of the directors to keep up with the changes in business and to anticipate the trends of the future. It is more vital today than ever before that the graduate should be prepared to meet the rapidly changing conditions and requirements of business. A liberal margin of security, favored by natural isolation, aided business during the period through which we have just passed, to the extent that rigid economy and a high degree of efficiency was not necessary. The rapid advances made in transportation and communication facilities have limited the isolation previously enjoyed, and in turn raised the standards of efficiency.

Those changing conditions open a broader field for engineering; the fundamental purpose of which is to achieve maximum efficiency at minimum cost. To accomplish that the engineer must enter the field of management and business control. With the new fields in view the schools must recognize the increasing importance of teaching subjects pertaining to the present day practise of business. Practical business courses should be added wherever it is possible to insert them.

Alfred H. Lovell in his paper on "Engineering Subjects in the College Program" (see Electrical Engineering for August 1932, p. 568–71) outlines some of the changes that have been made in the curricula of the technical schools to provide a more complete business training. Mr. Lovell points out that many of the schools have omitted foreign languages. Subjects that have been carried along for years by precedence and pride. To eliminate them is a step forward.

The value of shop work has been questioned as it is rarely used in practise today. Standardization has had much to do with eliminating the need for local work. Parts can be secured on short notice from any section of the country, it is no longer a local affair. Although useful, shop work will undoubtedly follow foreign languages and be replaced by subjects more applicable to the work encountered in the field.

There has been a general increase in the number of hours of training given in the department of English, which is very commendable. Report writing is more necessary today than ever before and it should be stressed in that department.

A question has been raised as to the value of surveying. Personally I would defend it as it is by nature a specialized course in mathematics and provides excellent and exacting training. It is also a very practical subject. There are, however, many subjects drafted from older engineering courses that can be replaced by those concerning present day practises. A careful survey of that part of the curricula will help to solve the time problem confronting most schools of engineering and develop a more practical course.

Yours very truly,
Orrin S. Vogel (A'29)
(Atlanta, Ga.)

## Consumption, Production, Distribution

*To the Editor:*

The American Engineering Council committee, in its progress report entitled "The Relation of Consumption, Production, Distribution" (see Electrical Engineering for June 1932, p. 373–7) has attacked an extraordinarily difficult and broadly comprehensive subject and has made a remarkably good presentation of preliminary results obtained within the scope of money and time which have been available to the committee. The results thus far obtained justify the expression of hope that the committee may be given support to continue its studies.

The statement made by the committee of its points of attack is an excellent résumé of 8 important threads. The characteristic of research and adaptation is intermixed with all these threads. In my opinion the committee has not made enough of that—research coming first and adaptation being the process of applying the principles brought out by the results of the research. This application of these principles to daily affairs must be made in 2 ways, one being direct and the other being through education. The education ties back again into means for improving the research and thereby making continuous progress. I agree with the committee that the objective which they have stated is physically possible for the whole of western civilization. To accomplish such realization, however, it becomes necessary to view the world as it is, with the modes of life, as they are, founded upon our present day development of science and invention. We cannot suitably support social practises for the present day by excerpts from and references to the writings of Adam Smith, Hume, Ricardo, John Stuart Mill and their associates covering a period of a century and a half beginning substantially a quarter of a millennium in the past. Over-constant adherence to the tenets of these ancient writers on economics is one of the reasons of inutility which pertains to modern day doctrines of political economy as pronounced by the economists. Political economy must be adapted to the modes of life of the age in which the application is made.

The committee wisely concludes that suitable economic readjustment can be realized to a large degree in the United States even if it is not contemporaneously accomplished throughout the western world. This view has an optimistic tinge, but its soundness is well worth proving and is likely to be proved in the near days. Certain aspects of many of the philosophical arguments that have been broadcast from economists and international bankers during the last 2 years have had an unfortunate influence besides being inaccurate. Iteration of the cry that the joint troubles of the western world must be cured before we can recover from our own financial and industrial difficulties is disturbing as well as false. It is particularly disturbing because it misleads our people into believing that they can do nothing for themselves, but must idle until the international bankers have extricated us. The contrary is the fact and we need exhortation to wring our salvation out of our own environment. The sounder attitude of the American Engineering Council's committee pronouncement is refreshing to observe. We cannot wait for the bankers and economists to clear up the international situation for the mutual good of the world, however active their efforts may be, before we put forth efforts to ameliorate our own individual situation. We must put our shoulder to the wheel of our own cart in the meantime, while the international efforts proceed. Our own agricultural follies need better attention; our own industrial methods need modification and our industrial products given a character which will enable them to be sold without the application of artificial draft; our public expenditures require pruning, and happily this view has taken strong hold throughout the nation within the last few months; common thrift needs a new recognition as good practise.

The committee expresses 6 aspects of popular explanations of our present difficulties, of which explanations they find each and all to be questionable and/or inadequate. It is my opinion that the committee is right, except partially for the items of speculation and of instalment buying under the conditions which characterized affairs in this country during a few years past. These conditions led to unchecked high pressure selling of manufactured products associated with instalment payments, which (associated with reckless agriculture) had a considerable share in engendering the origins of financial panic and depression which are upon us. Neither bankers nor economists raised the voice of warning while industrial plant and industrial man-power in various industries were being expanded to the level required by a forced and over accelerated selling basis that inevitably led ultimately to stagnant markets caused by the margins of family incomes being absorbed in payments for past purchases. Engineers associated with the industries shook their heads in doubt over the situation, but they must also bear their share of responsibility because they did not raise their voices in argumentative protest. This may be an evidence of moral weakness in an unexampled situation, but precedents were lacking and perhaps we may pass that weakness over if suitable prevision is shown in the efforts for reestablishment of stability.

The committee is quite right in stating that investment bankers and the speculative public both had definite responsibilities in the matter. The engineers also had responsibilities and part of that responsibility must rest with the engineering schools on account of their failure to press effectively into economic philosophy a recognition of those features which distinguish the modern world from the world of Adam Smith, Hume, Richardo, John Stuart Mill, and their contemporaries of over a century and a half ago. Unless we thus modify our political economy, we are likely to lose the enviable standard of living and of intellectual activity which exists among the generality of our citizens.

One of the difficulties that the committee's report lays before us is associated with an inference that long-time planning should be a feature of industrial finance as well as government finance. The problem is to secure this important achievement without recourse to a degree of bureaucratic government control that verges on the edge of despotism, although perchance a benevolent despotism. A benevolent despot can do many things successfully, but we are not likely to approve such a guide for our lives even during the period of establishing a new political economy which is requisite to meet present conditions of our life which is wrapped up with the developments of science and invention of the last dozen decades. We must surely set up our economic situation in independence for ourselves, but this can be accomplished without refusing due consideration of mutual benefits which may arise from associated contacts with other countries. The discussion of the shorter-hour week in the report of the committee shows means for accomplishing this end and the general observations of the committee also are reassuring, provided those directly affected have been provided with convincing incentives for properly joining the satisfactions of leisure with the advantages of productivity. All who retain faith in the effectiveness of the human mind feel sure that this can be achieved.

The responsibility of devising serviceable measures for fending against the recurrence of depressions such as the present one, and their trains of hardship and suffering, rests upon those of us who live in this decade. To meet their part of this responsibility it is necessary for the engineers to bring to pass a cooperation which joins our scientific, pragmatic attitude to the philosophical tendency of the economists.

The engineering departments of our great educational institutions are well established in, and should continue to expand their creative work in, the borderland which overlaps with the natural sciences of mathematics, physics, chemistry, and biology. They also work actively, but are not equally well established, in the borderland which overlaps with economics. The latter borderland—contrasted with studying, investigating, and guiding phenomena of nature related to physical phenomena—consists in studying, investigating, and guiding the economic and social uses of structures, power, machinery, communication of intelligence and transportation, and guiding the influence of engineering on modes and conveniences of life. We have a good start in this, but with less intensive cultivation than on the mathematical-physics side. The appropriate manner of carrying on is by statistical and scientific investigation to establish facts and relations that are now perceived only dimly or perhaps not yet perceived at all. This cooperation should be and can be as fully established as on the mathematics-physics border. The object is to place this economics side of engineering on the same altitude of rigorous examination and reasoning as now characterizes the science side of engineering in the engineering schools. Collaterally, the object is to develop more rigorous investigation in this now neglected or only loosely studied field, while scrupulously avoiding any detracting from the efforts on the science side.

Besides leading their students to familiarity with the theoretical tenets of science and economics, the engineering departments in the engineering schools have the obligation to translate to the students a scholarly engineering vision of the principles of science and economics embodied in the works of man wrought in materials such as metals, stone, wood, and fiber, and the influence on civilization which is concomitant to those embodiments. "Machines, the slaves begotten of man's thoughts" have done us relative good, but until the articulation of engineering into economics is worked out in the engineering schools of university rank as fully as the articulation which now exists with mathematics, physics, chemistry, and biology, there will be danger of the relative good becoming relative evil. I do not charge this fault to the economists, theirs being a philosophical field; but as previously said we, the engineers, must bring to pass a cooperation which joins our scientific, pragmatic attitude to their philosophic tendency. From such cooperation brought to pass in engineering schools of high level, we may validly hope for the solution of such complex problems, for example, as the periodic recurrence of acute unemployment, and the ultimate formulation of effective means for prevention. Illumination may be secured on many other subjects, such as the perplexing subject of the responsibilities for mutual welfare which pertain between corporations, their employes and their stockholders, when both employes and stockholders may be in large numbers and both groups in general being composed of people of small means.

When the engineering departments have accomplished this cooperation in the institutions of university level and have secured a communion with the economists of a level and order equal to our communion with the scientists, we will have established our buttresses in both sides of the field of engineering and will be in position to cultivate most serviceably the full area of industrial science and economics. This method of securing a restudy of the tenets of political economy so that the structure of economics adapted to our present day mode of life may be erected is feasible, and it is so promising of important results that I hope that it may command support from the A.E.C. committee.

Very truly yours,
Dugald C. Jackson
(F'12 and Past-president)
(Massachusetts Institute of Technology, Cambridge, Mass.)

## Reactive Power Units and Terms

*To the Editor:*

Mr. Irwin's letter (see Electrical Engineering, August 1932, p. 597–8) calling attention to the disregard of the internationally adopted "var" as the unit of reactive power is very timely. As if to vindicate Mr. Irwin's admonition, there are published, on page 589–90 of the same issue, engineering abbreviations that are officially endorsed by the A.I.E.E. In this list the "var" is conspicuously missing, whereas the "rva" is duly displayed.

The relation between "rva" and "var" is obvious. In "var" the "r" that stands for "reactive," is put after the "va" instead of before. In this manner a name is obtained which not only is easily pronounceable, but also contains the elements of definition of the unit it stands for; which is more than can be said of the names of most of the established units.

"Var," therefore, seems a perfectly rational name for the unit of reactive power, and it is difficult to see on what grounds objection could be made to its general use which ought to be promoted by the A.I.E.E.

The unit most commonly applied in practise will, of course, be the "kilovar," abbreviated "kvar," which also is missing in the "standard" engineering abbreviations referred to. One need only compare the brief term "kilovar" with the lengthy "reactive kilovolt-ampere," or with the cacophonous spelled variety: "rkva," to become converted to the name adopted by the International Electrotechnical Commission.

Very truly yours,
Arthur A. Bolsterli (A'23)
(145 Church St., Hamden, Conn.)

---

**Editor's Note:** As a comment on the above letter from Mr. Bolsterli, the following quotations from a letter sent to sponsoring organizations by Preston S. Millar (M'13), secretary of the American Standards Association's sectional committee on scientific and engineering symbols and abbreviations, are presented herewith:

"To the appendix of International Electrotechnical Commission recommendations attached to the report of the subcommittee on abbreviations for scientific and engineering terms, dated June 1932, which was distributed on June 3, 1932, to the sponsor organizations and to the members of the sectional committee, and which was submitted on June 15, 1932, to the American Standards Association, the following 3 units and abbreviations have been added:

"var (reactive volt-ampere)..................var
"kilovar (reactive kilovolt-ampere)...........kvar
"kilovarhour (reactive kilovolt-ampere-hour).kvarh

"These names of units and their abbreviations were officially adopted by the international Electrotechnical Commission at the plenary meeting held at Oslo, July 9, 1930. The list of I.E.C. abbreviations appended to the report of the subcommittee dated June 1932, was taken from an I.E.C. publication, which has not been revised since 1920. For this reason the 3 above terms and their abbreviations were unfortunately omitted. They are now added in order that the appendix may accurately represent the present day recommendations of the I.E.C."

It may be noted that the terms "var," "kilovar," and "kilovarhour" were officially adopted by the International Electrotechnical Commission on July 9, 1930. However, these terms are not consistent with American practise and have not been adopted as American standard. Therefore they were not included in the list of American tentative standard abbreviations published in Electrical Engineering for August 1932, p. 589–90. Further comments on this subject are invited.

# Overcompounded D-C Generators Without an Equalizer

*To the Editor:*

In this letter is discussed the division of load between 2 overcompounded d-c generators when the equalizer circuit is opened. The problem is not of importance practically but has considerable theoretical interest, as has been evidenced by the discussion aroused by the statement in "Direct Current Machinery," written by Harold Pender and published by John Wiley and Sons, that for a given total line current, if the speed of one generator increases after the equalizer has been opened, the current output of that generator decreases, and, the action being cumulative, the instability of operation without an equalizer is thus explained. Among the 5 other texts, in English, which have been consulted, there is virtually unanimous agreement that the converse holds, and the discussion mentioned above has centered on this point.

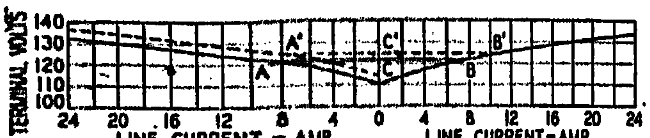

**Fig. 1. Voltage regulation curves of 2 d-c generators each rated 3 kw, 115–125 volts, 24 amp, 1,700 rpm**

To review briefly the minority argument which this letter attempts to justify further, consider Fig. 1, the voltage regulation curves (shown solid) of 2 generators supplying a total load current $AB$ at a voltage $OC$ when the current in the equalizer is zero. Opening the equalizer will have no effect on the system until some mechanical or electrical property changes. If for some reason the speed of generator 1 increases, the corresponding voltage regulation curve (dashed in Fig. 1) will be above the former curve, and the total load current, if it has not changed appreciably, will be represented by $A'B'$ ($= AB$ in magnitude). Hence, since $A'C'$ is less than $AC$, the current output of generator 1 will have decreased despite the increase in speed of this machine.

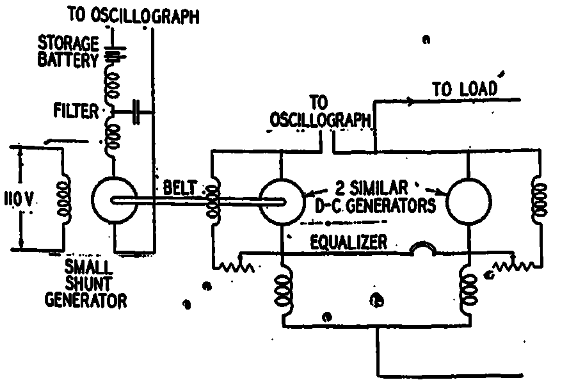

**Fig. 2. Connections for the 2 d-c generators represented in Fig. 1**

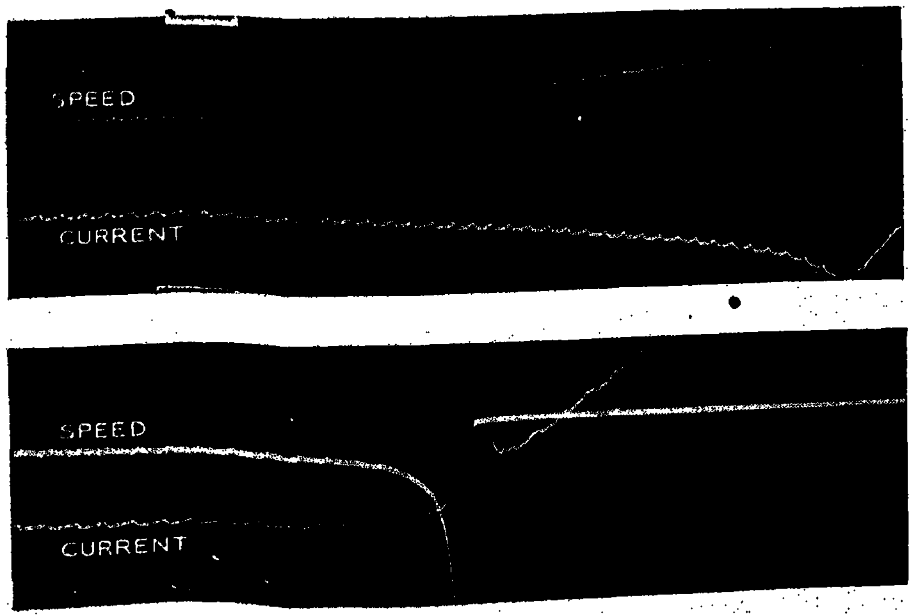
It is obvious that this argument can be only approximate, since the voltage regulation curves are determined for steady state conditions whereas the unstable condition of the system is essentially not a steady state condition. This has been the crux of many criticisms in which it has been contended that an increase in the speed of generator 1 increases the terminal voltage, hence causes that machine to increase its current output; the action is cumulative and consequently, according to this argument, the machine which increases speed ultimately carries all the load and may drive the other generator as a motor.

The oscillogram of Fig. 3 shows current and speed of one of a pair of similar generators (Fig. 2), the voltage regulation curves of which are pictured in Fig. 1. (Speed was measured by belting a small shunt generator to the machine and inserting a storage battery in the output circuit so that the voltage at the oscillograph was proportional to the difference between the actual speed and some datum near 1,700 rpm. An upward deflection of a curve on the oscillograms indicates an increase in the corresponding quantity.) The oscillogram is typical of many. It covers a time interval of 15 sec, and was obtained by simultaneously starting the photographic record and opening a circuit breaker in the equalizer, the current in the latter being zero. The portion of the oscillogram to the right of the peaks in the curves shows the readjustment following the reclosing of the circuit breaker in the equalizer. In this case the process took place comparatively slowly, the speed increasing while the current was decreasing. Fig. 4 shows the speed decreasing as the current increased. The action in this case took place rapidly after it was once started; the speed decreased sufficiently to cause a fuse in the corresponding oscillograph circuit to burn out, giving rise to the straight heavy curve in the right half of the figure, while the current, neglecting part of the curve due to overswing of the oscillograph element, increased rapidly and almost regularly.



**Figs. 3 (Above) and 4 (Below). Oscillograms of machines shown in the diagram of Fig. 2**

These oscillograms show conclusively that the majority argument given in the third paragraph of this letter cannot be of universal application. It cannot be claimed, however, that the oscillograms prove completely the other point of view. The problem is one which depends on many factors—the system would be unstable without an equalizer if the speeds remained constant—but the oscillogram of Fig. 3 does indicate that for the particular case the changes took place so slowly, comparatively, that the analysis using the steady state regulation curves would be expected to indicate at least qualitatively the action.

Very truly yours,

J. G. Brainerd (A'32)
(Moore School of Electrical
Engineering, University of
Pennsylvania, Philadelphia,
Pa.)

# Engineering Foundation

## A Reading List in Economics and Sociology

Engineers recently have exhibited a marked increase of interest in economics and sociology, and in the relation of engineering thereto. This interest appears to have become widespread and purposeful. To assist readers in these fields, The Engineering Foundation includes in its Research Narrative No. 190, the list of books and articles given below. The Engineering Foundation states that mention of a book in this list is not intended as an endorsement, nor should omission be taken to mean disapproval, nor has the order any significance. These books listed present varieties of subjects and views.

The Engineer in a Changing Society, W. E. Wickenden, Elec. Engg., July 1932, p. 465–71.

Sociology of City Life, Niles Carpenter, Longmans, Green & Co., New York, 1931. $3.90.

Population Problems, Warren S. Thompson, McGraw-Hill Book Co., New York, 1930. $3.75.

The Instincts of the Herd in Peace and War, William Trotter, The Macmillan Co., New York, 1930. $1.50.

The Epic of America, James Truslow Adams, Little, Brown and Co., Boston, 1931. $3.75.

The Direction of Human Evolution, Edwin Grant Conklin, Charles Scribner's Sons, New York, 1922. $2.50.

The Great Analysis, William Archer, Williams and Norgate, Ltd., London, 1931. 2 shillings.

## Research Procedure Committee Established

With the approval of the 4 principal engineering societies, and following a recommendation by the endowment methods committee of United Engineering Trustees, Inc., a research procedure committee has been established by The Engineering Foundation. The members of this committee appointed for the year 1932 and the societies which they represent are: Thaddeus Merriman, American Society of Civil Engineers; F. M. Becker, American Institute of Mechanical Engineers; W. H. Fulweiler, The American Society of Mechanical Engineers; L. W. Chubb (F'21), American Institute of Electrical Engineers; and E. DeGolyer, and D. R. Yarnall, Engineering Foundation.

The duties of this committee are to aid The Engineering Foundation in ascertaining and meeting the research needs of the 4 engineering societies and in making intelligent selections among the numerous projects in which these societies are individually and collectively interested.

# Personal

P. H. Chase (A'12, M'18) chief engineer of the Philadelphia Electric Company, Philadelphia, Pa., will continue as chairman of the Institute's technical committee on power transmission and distribution for the year following August 1, 1932. Mr. Chase is a native of New Hampshire. He was graduated from Dartmouth College in 1907 with the degree of A.B., received the degree of S.B. in E.E. from Massachusetts Institute of Technology 2 years later, and the degree of M.E.E. from the Graduate School of Applied Science, Harvard University, in 1910. Following the completion of these studies he joined the Public Service Electric Company of New Jersey as assistant to the superintendent of distribution for Newark, N. J., and for the greater portion of 2 years had general supervision over the commercial and railway substations of the Newark district. In 1912 he was transferred to the company's engineering department, at first reporting to the electrical engineer in charge of electrical design and construction of power stations, but shortly advancing to the office of assistant engineer, his work covering all phases of estimating costs, preliminary and final design of power stations and substations, making up specifications, and the supervision of construction. For 4 years he was chief electrical engineer for the American Railways Company. He joined the Philadelphia Electric Company in 1921 as assistant engineer of the transmission and distribution division; in 1928 he was advanced to the position of engineer in charge of the division. Mr. Chase has been active in several of the representative engineering societies; in the Pennsylvania Electrical Association he has been, in turn, chairman of the overhead systems committee, technical section chairman, treasurer, vice-president, and for the year 1926–7, president. He is past chairman of the Institute's Philadelphia Section, holds membership in the National Electric Light Association, the Illuminating Engineering Society, and The American Society of Mechanical Engineers. He also is a member of the Engineers' Club of Philadelphia, the Penn Athletic Club, and the Philadelphia Country Club. Other committee work for the A.I.E.E. has included service as a member of the committee on protective devices 1918–25, standards 1917–22, and technical program 1930–32. His membership on the power transmission and distribution committee dates from 1924 continuing in unbroken service, his chairmanship dating from 1930.

E. L. Moreland (A'11, F'21) of Jackson and Moreland, Consulting Engineers, Boston, Mass., has received his reappointment as chairman of the Institute's technical committee on transportation, to which he first was appointed in 1931. Mr. Moreland was born at Lexington, Va., and in 1905 was graduated from The Johns Hopkins University, Baltimore, Md., with the degree of A.B. in mathematics and physics. In 1908 he entered the employ of D. C. Jackson (A'87, F'12, and past-president) and W. B. Jackson (A'97, F'13) consulting engineers in Chicago, Ill., and Boston, Mass., and served as a personal assistant to Mr. D. C. Jackson, senior member of the firm. In 1912 Mr. Moreland was made manager of the Boston office of this firm, and in 1916 became one of the partners. From 1918 to 1919 he served first as captain and then major in the engineers corps, American Expeditionary Forces, on a technical board charged with the procurement of electrical and mechanical power for A.E.F. activities; also as technical executive on the War Damage Board, which was created to advise the American delegates to the Peace Conference with reference to damages to physical property caused in the allied countries by the war. Upon return from military service the partnership with D. C. Jackson was formed. The principal activities of the firm are as consulting engineers on the design and supervision of construction of power plants, and transmission and distribution systems for public utilities and large industrial plants; and on railroad electrifications, valuations, and rate investigations. Among the most conspicuous pieces of work handled by the firm recently have been the electrification of the Great Northern Railway through the Cascades and the electrification of the suburban service of the Lackawanna Railroad out of Hoboken, N. J. In Institute activities Mr. Moreland has served as chairman of the Boston Section; chairman of the electrical machinery committee's subcommittee on rectifiers, as well as on the full committee from 1929 to 1931; on the power generation committee 1929–31; and on the technical program committee 1931–32. He was the Institute's

F. O. SCHNURE

C. W. DRAKE

R. A. BEEKMAN

representative on and chairman of the sectional committee on mercury arc rectifiers organized under American Standards Association procedure, and has served on the Institute's standards committee. Mr. Moreland has contributed frequently to Institute and other engineering publications. He is a member of the Engineers' Club, both in New York and in Boston, and of the University and City Clubs in Boston.

**C. W. Rice** (A'14, M'24) assistant to the vice-president in charge of engineering, General Electric Company, Schenectady, N. Y., by recent appointment was made chairman of the Institute's technical committee on research. Mr. Rice, who is the son of E. W. Rice, Jr. (past-president of the Institute, a member for life, and honorary chairman of the General Electric Company, Schenectady, N. Y.), was born at Lynn, Mass., and removed to Schenectady after the consolidation of the Thomson Houston and Edison General Electric companies. Early schooling was through home channels and in small private schools; at the age of 13 he entered the second form of the Albany Academy, Albany, N. Y., and in the fall of 1906, Harvard University, from which he received his S.B. degree in 1910 and his M.E.E. degree in 1911. The fall of 1911 he entered the testing department of the General Electric Company at Schenectady, and the following December joined the consulting engineering department, where he worked under Dr. C. P. Steinmetz. June 1917 he was transferred to the company's research laboratory, where his work was principally on submarine detection devices, supersonic sound signaling, piezoelectric devices, heat convection work, and a no inconsiderable amount of radio research investigation. He holds a number of patents in these fields. In May 1927 he was again transferred, to become assistant to the vice-president in charge of engineering in the engineering general department, his present office. Mr. Rice's contributions to technical literature have been many. He belongs to many representative professional and scientific bodies, including The American Physical Society, the American Association for the Advancement of Science, the Institute of Radio Engineers, and the Acoustical Society of America, of all of which he is a fellow; and a member of the American Chemical Society and the Optical Society of America. He is an enthusiastic member of the Schenectady Glider Club and of the Edison Club. Mr. Rice has served the Institute on the following committees: educational, 1916–19; electrophysics, 1918–27; telegraphy and telephony, 1922–24; communication, 1924–28; and the research committee of which he has just been made chairman, 1928–32.

**C. W. Drake** (A'20, M'21) general engineer of the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., will continue to serve the Institute's technical committee on general power applications as its chairman for the coming year, in accordance with recent reappointment. Mr. Drake was born and educated in the city of Worcester, Mass., receiving his B.S. in E.E. from Worcester Polytechnic Institute in 1905. Leaving the New England section, he identified himself with the Westinghouse Electric and Manufacturing Company, at East Pittsburgh, and for the greater portion of 9 years worked with that organization's sales department as commercial or industrial engineer. In 1914 he was transferred to the Chicago office of the company, still as industrial engineer, but in 1919 returned to East Pittsburgh as general engineer of the industrial motor section. Since 1908 he has been in responsible charge of power and motor layouts for numerous industrial plants, paper mills, cement plants, and rubber mills. His work covered also the making of reports and estimates and supervision of installations and tests, leading to developments for special application of new types of drives and controls. He also did considerable work with central stations, assisting them in building up their motor load. The carrying out of tests and investigations took him practically to all parts of the United States. For over a year he had charge of a section of the Westinghouse company which was devoted to general engineering on electric welding, oil well machinery, and sugar mill equipment. His committee work with the A.I.E.E. includes 3 years on the committee on industrial and domestic power, 8 years on the general power applications committee, and 2 years on the technical program committee.

**F. O. Schnure** (A'23) who since 1916 has been identified with the Bethlehem Steel Company, Sparrows Point, Md., where he is now electrical superintendent, has been chosen as chairman of the Institute's technical committee on applications to iron and steel production for the current year. Mr. Schnure was born at Milton, Pa., and was graduated from Bucknell University with his B.S. in E.E. in 1914; his E.E. degree was conferred upon him in 1919. For a short period during 1914 he was with New York Railways as inspector of subway conduit construction. Then he joined D. C. and W. B. Jackson of Boston, Mass., as inspector and supervisor of overhead lines and power house appraisal of the Public Service Electric Company of New Jersey. The latter part of 1915 he joined the Pennsylvania Railroad Company at Altoona, Pa., as draftsman on power house design and layout. This was his position immediately preceding his joining the Bethlehem Steel Company, which he entered for miscellaneous electrical test work on maintenance and construction. After a year and a half in charge of electrical layout on a 50,000,000 dollar steel plant extension and $2^{1}/_{2}$ years as general foreman of electrical construction, he became foreman of the electrical repair shops. From this position he became assistant superintendent of the electrical department, later to be made superintendent, the office which he now holds. Mr. Schnure is also a member of the Institute's power generation committee, 1931–33, and in 1930 was elected president of the Association of Iron and Steel Electrical Engineers, a body in which he has been active over a considerable period of years, having served as chairman of its Philadelphia section in 1926–27, as a member of various of its committees. While in Baltimore, he served upon the executive committee of the A.I.E.E. local Section; also as a member of the educational committee of the Baltimore Chamber of Commerce during the years 1928–32. He has been a frequent contributor to technical literature both in papers before these several associations as well as through the technical press, writing on a variety of subjects dealing with the application of electricity to the steel industry.

**R. A. Beekman** (A'13, M'27) engineer of the federal and marine department of the General Electric Company, Schenectady, N. Y., continues for the ensuing year as chairman of the Institute's technical committee on applications to marine work. Mr. Beekman is a native of St. Louis, Mo., and received his B.S. in E.E. from the University of Missouri in 1910. July of that year he entered the testing department of the General Electric Company, from which he was transferred to the marine engineering department, now the federal and marine department. He holds several patents appertaining to electric ship propulsion; is a member of the Naval Architects and Marine Engineers, and has served on the Institute's committee on marine work since 1919, having been chairman since 1930. He also has been the Institute's representative on the American Marine Standards Committee since 1926. As chairman of the Institute's marine committee he is automatically a member of the Institute's technical program committee. Intimately associated with the General Electric Company's marine activities since 1912, he has spent considerable time at sea.

W. S. Culver (A'28) who for 47 years has been in the employ of the General Electric Company and its predecessors, and whose latest position with that company has been as district engineer of its East Central district with headquarters at Cleveland, Ohio, has retired from active service effective October 1, 1932. Mr. Culver has been a pioneer in the electrical industry, his first outside work being the installation of a 35-light incandescent generator. He was a close friend of Charles Francis Brush, of Cleveland, Ohio, the first man to bring out a commercial arc light system in this country and the founder of the old Brush Electric Company. Mr. Culver's first commercial connection in 1885. Mr. Culver also has spent considerable time in Manila installing electric light plants there. Upon his return to the United States he worked for awhile at the General Electric Company's Lynn plants, going to the central district then located in Cincinnati, Ohio, in 1902. His appointment as district engineer took place in 1907.

C. F. Hirshfeld (A'05) who is chief of the research department of the Detroit Edison Company, Mich., has been chosen vice-president of The American Society of Mechanical Engineers, an organization of which he has been a member since 1905. Always active in committee work, Doctor Hirshfeld has served the National Electric Light Association as chairman of its prime movers committee and of its engineering national section. For several years he was a representative of the electric light and power group of the American Standards Association; he has served on many committees of the A.S.M.E. In the committee work of the Institute, Doctor Hirshfeld has served on the following: industrial and domestic power, May–August 1922, power stations 1922–24, power generation 1924–31, standards 1923–30, and electrical machinery 1926–27. The degree of doctor of engineering was conferred upon him by Rensselaer Polytechnic Institute, Troy, N. Y., June 1932.

T. W. Carraway (A'21, M'32) who was vice-president of the Schwitzer-Cummins Company, Indianapolis, Ind., was transferred to Providence, R. I., as manager of the unit cooler department of the Grinnell Company, Inc., when the unit cooler, unit heater, and automatic valve business of Schwitzer-Cummins was purchased by Grinnell. Mr. Carraway has been unusually successful in the design and development of unit coolers and automatic equipment and is inventor of the Carraway automatic packless valve.

L. E. Underwood (A'03, M'13) who has been serving the General Electric Company at Lynn, Mass., as managing engineer of the stationary motor engineering department now has been appointed manager of the Pittsfield (Mass.) works. Mr. Underwood initiated his service in the stationary motor engineering department in 1899; was made chief engineer in 1915, and in 1927 managing engineer of the consolidated motor department in charge of engineering and manufacturing.

J. E. H. Stevenot (A'13, M'17) vice-president and general manager of the Philippine Long Distance Telephone Company, Manila, P. I., by executive orders issued by Governor-General Theodore Roosevelt under date of July 14, 1932, was made a member of a special committee on coordination of electrical communications in the Philippine Islands. This committee will meet at least once every month and submit its report to the Secretary of Commerce and Communications.

C. S. Lumley (A'23, M'29) who was electrical engineer for Smith, Hinchman and Grylls, Detroit, Mich., recently removed to Brookline, Mass., to become executive engineer of the Longwood Towers Corporation. Mr. Lumley has been with the Detroit interests, in charge of the municipal power plant project for the past 6 years; he also was chairman of the Institute's Detroit-Ann Arbor Section and a member of its membership and meetings and papers committees.

G. C. Neff (M'16) vice-president of the Wisconsin Power and Light Company, succeeds M. J. Insull (A'99) as president of the Middle West Utilities Company, Chicago, Ill., according to information recently made public. Mr. Neff has been chief operating executive of the Wisconsin Light and Power Company for several years. He has been active in the National Electric Light Association and in the promotion of rural electrification.

J. M. Barry (A'11) heretofore vice-president in charge of operation for the Alabama Power Company, Birmingham, Ala., recently succeeded to the office of vice-president and general manager. He has been with the company since 1923, when he became manager of its southern division; thereafter he was made manager of retail operation, and in May 1927 he took up his duties as vice-president in charge of operation.

C. W. Fick (A'16, M'25) who has been serving the General Electric Company's East Central district at Cleveland, Ohio, as assistant district engineer, effective October 1, 1932, became district engineer, succeeding W. S. Culver (A'28), retired. Mr. Fick prior to becoming assistant to Mr. Culver was northwestern engineer for the General Electric Company at Portland, Ore.

C. W. Adams (A'20) formerly with the United States Graphite Company of Saginaw, Mich., became affiliated on September 15, 1931, with the Speer Carbon Company of St. Marys, Pa., in the capacity of sales and consulting engineer at Saginaw, Mich. (Electrical Engineering for August 1932, p. 603, erroneously stated Mr. Adam's position and address.)

W. S. Gifford (A'16) president of the American Telephone and Telegraph Company, New York, N. Y., under date of August 5, 1932, withdrew from his work as active director of the President's organization on unemployment relief at Washington, D. C., and will again devote his full time to the office of president of his company.

J. E. E. Royer (A'15) who recently became vice-president as well as general manager of the Washington Water Power Company (Electrical Engineering, July 1932, p. 530) at a recent meeting of the Northwest Electric Light and Power Association was elected president of that organization.

Gerald Deakin (A'07, M'13) formerly vice-president and European technical director of the International Standard Electric Corporation at London, has returned to New York City to become technical director in charge of manufacturing and laboratory companies of the International Telephone and Telegraph Corporation.

E. H. Pemberton (A'32) who in the spring of 1931 was graduated from the General Electric Company's general course consisting of higher studies in electrical engineering and principles of business and management, now is teaching mathematics and physics at the Las Animas High School, Las Animas, Colo.

J. J. Albright, Jr. (A'21) previously manager of the power distribution central division of the Niagara Hudson Power Corporation, and more recently with the Niagara Lockport and Ontario Power Company at Syracuse, N. Y., now has joined the Syracuse Lighting Company of that city.

P. M. Downing (A'98, M'08) first vice-president and general manager of the Pacific Gas and Electric Company, San Francisco, Calif., recently was appointed chairman of the national sales section, an outgrowth of the former commercial section, of the National Electric Light Association.

Albert Brunt (A'14) who for some time has been director of the Societa per Construtioni Elektromechaniele di Saronno, Saronno, Italy, recently returned to Holland where he graduated from the Delft University in 1906, to become export manager of the Werkspoor, at Amsterdam.

Dean Harvey (A'04, M'13) has been chosen by The American Society for Testing Materials to serve as its chairman of committee B-4 on electrical heating, electrical resistance and electric furnace alloys. He also is vice-chairman of its committee D-9 on electrical insulating materials.

Alex Dow (A'93, F'13) president of the Detroit Edison Company, and a past-president of The American Society of Mechanical Engineers, has been appointed chief of the Detroit Ordnance District, a most important locality in Ordnance industrial procurement organization.

Thomas Spooner (A'12, F'29) manager of the central division research laboratories of the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., recently became chairman of the American Society for Testing Materials committee A-6 on magnetic properties.

H. S. Vassar (A'06, M'18) laboratory engineer of the Public Service Electric and Gas Company, Newark, N. J., recently was made a member of the executive committee of The American Society for Testing Materials. His history with his present company dates from the year 1903.

H. V. Dobson (A'28) city electrical inspector for Santa Barbara, Calif., was chosen to serve as chairman of the committee in charge of arrangements for the annual convention of the International Association of Electrical Inspectors held in Santa Barbara September 12–14, 1932.

M. V. Watson (A'07) vice-president and general manager of the West Coast Power Company, Portland, Ore., at a recent meeting of the North West Electric Light and Power Association was elected a member-at-large of the executive committee to represent utilities.

A. S. Moody (A'09) northwestern manager of the General Electric Company, Portland, Ore., was elected a member-at-large on the executive committee of the Northwest Electric Light and Power Association, in Portland, Ore., to represent the manufacturers.

C. W. Bates (A'08, M'13) who for the past year or so has been in the research department of Leeds and Northrup Company, Philadelphia, Pa., in August 1932 became a member of the technical staff of The Franklin Institute Museum in that city.

A. B. Day (M'16) president and general manager of the Los Angeles Gas and Electric Corporation, Los Angeles, Calif., is a member of the recently appointed executive committee of the Pacific Coast division of the National Electric Light Association.

H. L. Curtis (A'21, F'26) principal physicist of the United States Bureau of Standards, Washington, D. C., recently assumed the chairmanship of the American Society for Testing Materials committee D-9 on electrical insulating materials.

L. T. Merwin (A'10) vice-president and general manager of the Northwestern Electric Company, Portland, Ore., was named vice-president of the Northwest Electric Light and Power Association at the executive meeting July 30, 1932.

Frederick Aemmer (A'27) who has been serving the New York Edison Company, New York, N. Y., as assistant engineer, recently was made operating manager of Kraftwerke, Oberhasli Power Company, Innertkirchen, Switzerland.

E. W. Feller (A'27) who has been in the operating department of the Pennsylvania Water and Power Company at Holtwood, Pa., has gone to Safe Harbor, Pa., to join the operating department of the Safe Harbor Water Power Corporation.

A. S. Goldman (A'28) who was formerly purchasing agent for the People's Light and Power Corporation, New York, N. Y., recently was made division manager of the California Public Service Company, at Fort Bragg, Calif.

R. W. MacGregor (A'30) who at one time was affiliated with the International General Electric Company, at Schenectady, N. Y., now is in the commercial department of the Winters National Bank and Trust Company, Dayton, Ohio.

Tom Hairston (A'30) who has been associated with the Public Utilities Commission of the District of Columbia, Washington, D. C., recently accepted a position with the Gustav Hirsch organization of Columbus, Ohio.

H. E. Dexter (A'14, M'17) who for some years has been assistant general commercial manager of the Central Hudson Gas and Electric Company, Poughkeepsie, N. Y., recently appointed as its general commercial manager.

H. K. Munroe (M'17) who was vice-president of the Continental Pipe Manufacturing Company, Seattle, Wash., now is vice-president of the American Plumbing and Steam Supply Company, Tacoma, Wash.

R. F. Pack (A'11, M'12) president of the Northern States Power Company, Minneapolis, Minn., has received appointment to chairman of the rehabilitation committee of the Ninth Federal Reserve District.

H. L. Paulding (A'31) who for some time has been interested in the development of printing telegraph apparatus, recently became electrical engineer of Dow, Jones and Company, Inc., New York, N. Y.

E. A. Wagner (A'08, F'27) has retired from the office of manager of the General Electric Company's Pittsfield works, as recently announced through company channels.

L. B. Bender (A'20, M'27) major of the Signal Corps, U.S. Army, Army War College, Washington, D. C., has been transferred to Fort Hayes, Columbus, Ohio.

J. T. Danko (A'31) has removed from McKeesport, Pa., to become instructor in mathematics and electricity at the Aliquippa (Pa.) high school.

R. A. Menendez (A'31) recently became assistant to the electrical engineer of the Harnischfeger Corporation, operating in the city of Milwaukee, Wis.

# Obituary

Magnus Washington Alexander (A'12, M'14) for the past 16 years president of the National Industrial Conference Board, Inc., New York, N. Y., died at his home in New York City on September 10, 1932, of heart attack. He was 62 years of age. Doctor Alexander was a native of New York City, but his general education was acquired in Vienna, Austria, first attending gymnasium there and later a college of mechanical engineering and mining academy for metallurgical engineering. In 1894 he joined the Weston Electrical Instrument Company, Newark, N. J., as draftsman, changing the following year to become draftsman and section chief draftsman on d-c motors and generators, and transformers for the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa. In 1899 he removed to Chicago to become chief draftsman for the Siemens Halske Electric Company for one year, after which he joined the General Electric Company, West Lynn, Mass., first as engineer in charge of the drawing office for 8 years and then on economic and executive work, including educational activities. His service with the General Electric Company extended over a period of 18 years. In 1918 he was made engineer on economic issues in a consulting capacity. In 1916 he helped to organize the National Industrial Conference Board, devoted to industrial planning and research, and by 1919 he was giving the major portion of his time to its development. In 1920 the board moved its offices from Boston, Mass., to New York City, but during a portion of the 4 years just prior to his return to New York, Mr. Alexander was prominent also as chairman of the Massachusetts Commission on Old Age, Annuities and Pensions and as a member of the Massachusetts Commission on Compensation for Industrial Accidents. As the scope of the industrial conference board broadened, Mr. Alexander more and more assumed the rôle of spokesman for some of the greatest industries of the nation. In Washington in 1919 he opposed the principle of collective bargaining between capital and labor. In 1918 Mr. Alexander opposed the circulation of a school book called "Lessons in Community and Private Life" the foreword of which was written by President Wilson, the basis of his opposition being that it taught the children to favor social insurance, labor unionism, and governmental control of private activities. In November of 1930 Mr. Alexander criticized the retailers for not having cut their prices, stating that "when retail prices have reached a sufficiently low level and not sooner will there be a distinct inducement for the public to buy." Last April, in addressing the graduating class of the General Society of Mechanics and Tradesmen, he said, "When all is said and done the conclusion would seem to be justified that the basic cause of the recent colossal collapse was overindulgence in the expansion of industrial plants and equipment, in production, in stimulation of production by excessive advertising, high-pressure salesmanship and instalment selling; overindulgence in spending, and overindulgence in speculation."

**Grover Cleveland Sutton** (A'11) a member of the Institute's Spokane Section and at the time of his death vice-president of the General Machinery Company, Spokane, Wash., died in that city August 2, 1932. Mr. Sutton was a native of Worton, Md.; he studied electrical engineering first by a correspondence school course; then attended Washington College at Chestertown, Md., from which he won his A.B. degree, and still later studying at Carnegie Institute of Technology, then known as the Carnegie Technical Schools. His first commercial affiliation was as chief engineer of the Chestertown Electric Light and Power Company, Chestertown, Md. This was during his last 2 years at college. In 1907 he became an engineering apprentice with the Westinghouse Electric and Manufacturing Company, at Pittsburgh, Pa., and 2 years later was sent to Spokane, Wash., as salesman for this company. The years 1910–12 were spent as erecting and operating engineer in saw mill electrification, after which he became purchasing agent for saw mill, logging, and all related operations. In this capacity he was responsible for all engineering in connection with an extensive logging and lumber manufacturing business, advising as to the necessity of purchase on all matters coming within his jurisdiction.

**Charles Shirley McGill** (A'21) who has been serving the Delaware Power and Light Company of Wilmington, Del., as plant superintendent, died the latter part of August 1932. Born at Leesburg, Loudoun County, Va., Mr. McGill attended the Leesburg Academy, and later the East High School in Washington, D. C. He took a private course in higher mathematics under Prof. Brantz Rossell at Johns Hopkins University, and further studied mathematics and electrical engineering by correspondence. In 1895 at the age of 18 he became a shop apprentice with the Metropolitan Railway Company, Washington, D. C., remaining there until 1897 when he was engaged as a switchboard operator by the Columbus Edison Company at Columbus, Ohio. In 1900 he left Columbus to accept work as apprentice and salesman of the Westinghouse Electric and Manufacturing Company, to operate both at Pittsburgh, Pa., and Baltimore, Md. Four years later the Houston Coal and Coke Company of Elkhorn, W. Va., made him its chief electrician; he simultaneously performed like duties for the Thacker Coal and Coke Company, at Thacker, W. Va., installing and placing in operation power house and mine haulage for these 2 companies. In 1907 the Western Electric Company, Cincinnati, Ohio, made him assistant sales manager, but in 1909 he changed to become sales engineer for Allis-Chalmers Manufacturing Company, Cleveland, Ohio. Returning again to Cincinnati in 1911 he became branch manager of the Crocker-Wheeler Company, 4 years later to return to the Allis-Chalmers Manufacturing Company, this time at Huntington, W. Va., as branch manager. In 1916 he took up power engineering with the Wilmington and Philadelphia Traction Company, and a year later was advanced to the office of electrical superintendent.

**Max Kushlan** (A'28) electrical squad chief of the New England Power Construction Company, Mattapan, Mass., died in Boston, Mass., August 1932, following an operation. He was born at Minsk, Russia, but came to the United States at an early age and attended the English High School at Boston, Mass., Tufts College, at Medford, Mass., and the Massachusetts Institute of Technology, Cambridge, Mass., from which latter institution he received his S.B. degree. From 1909 to 1910 he was a cable tester for the Boston Elevated Railway Company; then he joined Stone and Webster, Inc., as a draftsman remaining with this organization until 1912 when he went as assistant mechanical engineer to the Goldschmidt Detinning Company, East Chicago, Ind. Remaining there until 1913, he joined Sargent and Lundy, Chicago, Ill., as electrical draftsman; 2 years later he became engineering draftsman for the City of Chicago. In 1916 his title was changed to designing engineer, city of Chicago, and he was made assistant to the head of the division of bridges, in responsible charge of design of mechanical and electrical equipment for bascule bridges, his work including reports and specifications. The year 1920 found him electrical engineer of the Bascule Bridge Company, Chicago, directing electrical design work in the office and supervising the work in the field. He also represented his firm at conferences with clients. In 1921 he established his own business as engineer and contractor, but the following year joined the Brooklyn Edison Company, Brooklyn, N. Y., as electrical checker, a service which he continued until 1923, when Stone and Webster, Inc., made him its electrical designer in responsible charge supervising and checking electrical drawings and estimates in connection with power station design. Mr. Kushlan was the author of "The Gas Motor" and "Freehand Drawing," and contributed articles to technical magazines.

**James Andrew Shepard** (A'13) assistant general manager of the Roan Antelope Copper Mines, Ltd., Luanshya, Northern Rhodesia, died July 13, 1932, following a hospital stay of some 10 days. He was born in Deming, New Mexico, in 1889 and was graduated as an electrical engineer from the Rose Polytechnic Institute, Terre Haute, Ind. From there he entered the electrical department of the Detroit Copper Mining Company, Morenci, Ariz. Upon leaving Morenci, Mr. Shepard served the Public Utilities Companies in Deming and Tucson, Ariz., and was later appointed manager of the Bisbee-Naco Water Company. In 1926 he joined the Phelps Dodge Corporation at its Copper Queens branch at Bisbee, Ariz., first as assistant general manager, and when the general superintendent was transferred to Northern Rhodesia, Mr. Shepard took over his duties. In 1929 Mr. Shepard went with the Roan Antelope Copper Mines, Ltd., as assistant general manager, where he was greatly respected by every one with whom he came in contact.

# Local Meetings

## Future Section Meetings

**Dallas**

October 17—Vibration of Electrical Conductors, by R. A. Monroe, Aluminum Co. of America. Illus.

**Lehigh Valley**

October 14—Electrons at Work and Play, by Phillips Thomas, Research Engr., Westinghouse Elec. & Mfg. Co. Meeting to be held at the Traylor Hotel, Allentown, Pa.

**New York**

October 14—Opening meeting of power group; meeting devoted to "Serving the Electric Consumer." The utility's problem will be presented by H. R. Searing, The New York Edison and United Electric Light and Power Companies, while the contractor's problem will be discussed by Allan Coggeshall, President, Hatzel and Buehler, Inc. Discussion of items such as demand factor, power factor, voltage requirements, motor starting currents, and attendant costs will illustrate that each of the 2 agencies, utility and contractors, must work with an understanding and appreciation of the functions and problems of the other, in order that service of a high standard may be rendered. The meeting will convene at 7:30 p.m., and will be adjourned promptly at 9:30. Non-members are welcome. Discussion is open to all. The location will be Room 1, Fifth Floor, Engineering Societies Building.

**Pittsfield**

November 1—Japan, China, and the White Man, by Upton Close.

November 15—Air Conditioning—Perfect Weather in Your Home 365 Days a Year.

## Past Section Meetings

**Mexico**

Vacuum Tubes and Applications to Industry, by C. Santacruz, Genl. Elec. Co. Illus. Dinner. Aug. 26. Att. 42.

**Milwaukee**

Public Works, by Maj.-Genl. Lytle Brown, U.S. Army. Joint meeting with the Engrs. Soc. of Milwaukee.

**Pittsfield**

Excursion. Aug. 31. Att. 227.

**Spokane**

Adventures in Science, by E. L. Manning, Genl. Elec. Co. July 1. Att. 450.

**Toledo**

Discussion of activities for coming year. Sept. 9. Att. 27.

## Past Branch Meetings

**University of California**

Dr. L. E. Reukema, counselor, reported on the summer convention held at Cleveland, O. Dr. L. F. Fuller outlined changes and activities in the elec. engg. dept. during the coming year. Motion pictures. Aug. 24. Att. 70.

**Drexel Institute**

The Therapeutic Value of X-Rays, by Edward Cliver, student. Aug. 16. Att. 7.

# Employment Notes

## Of the Engineering Societies Employment Service

## Men Available

### Construction

E.E., grad., 35, married; 19 years experience as electrician, construction foreman, substation operator. Elec. welding experiments; 3 yr. utility, drafting and engg.; $3^{1}/_{2}$ yr. Western Elec. mech. and elec. designs. Wiring diagrams and genl. industrial plant construction. Best references. Scandinavian languages. D-1393.

GRAD. E.E., 29; 5 yr. supervisory construction, design, estimating, and field engg. experience on super-pwr. plants and substations; 4 yr. industrial pwr. plant operation, elec. construction and maintenance experience; ry. electrification construction experience. C-4428.

PRACTICAL ELEC. CONSTR. CHIEF, 32, single, 14 yr. experience in construction also maintenance work. Last 4 yr. in Latin America. Can speak Spanish and German fairly well. Available immediately. Location, immaterial. C-2101.

YALE GRAD., 1927, B.S. in E.E., desires engg. position or teaching, $1^{1}/_{2}$ yr. experience testing ry. ltg. equip.; $3^{1}/_{2}$ yr. design and application of outside plant hardware in natl. utility. Also experience in operation of small pwr. plant. Location preferred East. D-1305.

ELEC. CONSTR. ENGR., with 10 yr. practical experience in elec. constr. of new and old bldgs., including estimating, field engg. and designing. Have had complete charge of elec. constr. on many bldgs. in N. Y. City and can furnish the best of references. Available at once. A-850.

### Consulting

CONS. ENGR., Grad. E.E., 31, with Am. and S. Am. experience in distribution and transmission design and construction, appraisals, meters, testing, purchases and stores, and pwr. sales. Desires opening in consulting office. Location, immaterial and salary secondary. D-1383.

### Design and Development

E.E., 31, single, Am., 4 yr. experience in design of sound reproducing equip., 5 yr. of practical ry. signaling work in field and office, part in foreign countries, speaks and writes German, Spanish and French, wishes engineer's position in the elec-mech. field, location anywhere. Available immediately. C-5056.

SWITCHBOARD DESIGNER, 29, married, 6 yr. experience in design of a-c. and d-c. pwr. plant switchboards, motor controls, wiring schemes, switchboard: estimating, sales, erection supervision and engg. Also 3 yr. experience on manual and automatic tel. switchboards. Desires position as designer, estimator or sales engr. Location in East preferred. D-1423.

ELEC. DESIGNER, 30, married, 5 yr. experience with telegraph company, competent draftsman; speaks Spanish correctly and fluently. Will accept domestic or foreign location. Available at once. D-1442.

E.E., 10 yr. experience. B.S. Worcester P. I. 1922. E.E. 1924. A'25, M'32, Section chm. '32 A.I.E.E. Single, 32, 8 yr. experience Westinghouse transformers and auxiliaries, 2 yr. executive experience. Possesses inventive and natural ability, personality and adaptability. Capable of assuming responsibility. Location, immaterial, New England preferred. D-1443.

ELEC. DESIGNER, 32, married, equivalent of col. education, best of references, 14 yr. experience in design of hydroelectric and steam pwr. plants, auto. ry., high and low tension substations and low tension network systems. Available at once. Location, immaterial. B-8628.

E.E. GRAD., 30, married 5 yr. with Westinghouse design and application of protective relays, 3 yr. with utility as switchboard designer and kindred work. Desires position with utility or mfr. Location preferred, Southwest, but anywhere acceptable. Available immediately. D-1476.

B.S. in E.E. 1929. 34 months of Westinghouse test including industrial motors, large generating apparatus and ry. motors. Interested in securing a position with a large industrial concern or utility. Location vicinity of New York. Available immediately. D-1455.

### Executives

E.E., univ. grad., 4 yr. experience, drafting, design, construction and engg. of modern hydro and steam pwr. plants, substations and ry. electrification, $5^{1}/_{2}$ yr. with leading mfg. concern in engg. of automatic and manual switchgear equip. Foreign languages. Desires position with utility, engg., mfg. or ry. concern. Location, immaterial. B-7938.

ELEC. AND ILLUM. ENGR., Mem. A.I.E.E., I.E.S., 26 yr. experience commercial and industrial wiring and construction. Would like to connect with progressive contractor; estimating, engg., supervising, soliciting and selling work on quality rather than on price. Moderate salary to grow with business. Any location. C-8460.

E.E. GRAD., 29, married, 7 yr. broad experience, powerhouse, substation and transmission line design; major apparatus application, cost estimate, and equipment specifications. Excellent references. Desires connection with holding company, utility or mfr. D-678.

CHIEF ENGR., 42, married, practical, aggressive executive, with 20 yr. experience in design, development, production, sales and application of elec. material handling and factory equip. Available now. A-445.

ASSOC. A.I.E.E., B.E.E., '21, 39, single, $2^{1}/_{2}$ yr. additional study civ. engr.; 3 yr. steam R.R. valuation, elec. and mech. branch; 11 yr. track dept., large st. ry. property. Field engr., track supervisor and asst. to supt. maintenance; 5 yr. estimator track constr. semi-working knowledge spec. trackwork design. Location optional. D-1392.

TO AM. ENGG. CONCERNS operating in Spanish speaking countries—B.S. in E.E., 1929, single; 3 yr. genl. engg. experience, including erecting and testing pwr. equip.; conducting illum. and voltage surveys. Can speak English and Spanish equally well. Tech., administrative type of individual. D-1462.

E.E., M.E., 22-yr. experience, designing, constr. pwr. plants, substations, transmission, distribution systems, and industrial plants. Three yr. charge purchasing engg. equip., foreign interests; 3 yr. exec. experience charge engg. dept. large utility. English, German, Russian, Armenian, Turkish languages. Available immediately. D-84.

E.E., 34, 10 yr. experience covering design, cost estimating and equip. specifications of pwr. plants, copper refineries, indoor and outdoor substations, transmission lines and industrial work. Also 1 yr. experience as asst. research engr. with cable co. C-5478.

E.E., grad., 34, single; 7 yr. experience with utilities, estimating and designing transmission lines, substations and distribution systems; also reports and valuation of elec. properties. Speaks and reads German. Available immediately. Location, immaterial. B-8649.

ENGR. EXEC., M.E., M. I. T. grad.; 17 yr. broad experience in mfg. design and layout of plants; maintenance, mgmt. of machine shops, foundries, woodworking plants and other industrial plants. Purchasing. Traveled as mfrs. representative abroad. Knowledge of Russian, German. B-2589.

E.E. also B.S. in M.E. and C.E., 37; married. Splendid 15-yr. record of engg. accomplishments including design, development, application, supervision and exec. charge. Best reference. Desires opportunity where education and experience will prove valuable. Correspondence invited for more particulars. D-1494.

EXEC., univ. grad., 16 yr. experience in engg., mfg. and sales. Will consider proposition on salary or salary and commission basis. Location any place in U. S. A., although New York or vicinity preferred. Available at once. Prepared to travel. A-3946.

GRAD. ELEC., HYDROELEC. ENGR., 31, married, 2 yr. experience marine elec. installation; 8 yr. design, construction of steam, hydro pwr. plants, outdoor, indoor substations, transmission, distribution lines, wiring diag., indus. plants, office bldg., estimating, preparation of specifications. Desires position, utility, cons. engg. firm, industrial concern. Consider any location. Available immediately. D-212.

### Inspection

ELEC. GRAD., 38, single; 6 yr. experience factory testing—W. E. & M. Co., E. Pittsburgh, Pa.; 1 yr. steel co. installing and testing elec. equip. Six months factory inspection of transformers, $2^{1}/_{2}$ yr. genl. inspection of elec. equip. with insurance co. Good reference. Available immediately. Any location. D-1461.

### Instruction

E.E. GRAD., 1929; 3 yr. instructor of economics of engg. Grad. work in economics and business administration. Desires to teach economics and related subjects to engrs. or to get into any kind of engg. mgmt. Available immediately. Location, immaterial. D-1405.

PHYSICIST, 49, married, Ph.D.; 7 yr. univ. teaching experience, Yale, U. of Ill.; 1 yr. study Rutherford, Eng.; 15 yr. experience, directing, carrying on research in heat transmission and phases elec. and mech. lines 2 large industrial concerns. Present position being discontinued. Desires position of responsibility, univ. teaching or industrial research. D-1366.

### Junior Engineers

E.E. GRAD. with honors, 1932, Ala. P. I., 23, single. Speaks fluently Greek and English. Desires experience and is willing to work. Worked way through col. Excellent references. Interested in sales work. Glad to hear from you. D-1384.

ELEC. INSTRUMENTS, 6 yr. mfg. experience pyrometer indicators, controllers and recorders, specialized on galvanometer construction. B.S. 1922 chem. engg., Pennsylvania St. Col. At Columbia 1931–1932 studying elec. and physics. Single, 31. Any line elec. mfg., testing, etc. Location, New York or East. D-1382.

## ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.
San Francisco

205 West Wacker Drive
Chicago

31 West 39th St.
New York

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

**Men Available.**—Brief announcements will be published without charge; repeated only upon specific request and after one month's interval. Names and records remain on file for three months; renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

**Opportunities.**—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

**Voluntary Contributions.**—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

**Answers to Announcements.**—Address the key number indicated in each case and mail to the New York office, with an extra three-cent stamp enclosed for forwarding.

GRAD. E.E., Rensselaer P. I., 1932; 22; single. Desires any kind of work in the elec. field. Location, immaterial. Available at onec. D-1397.

MOVING PICTURE SOUND staff position desired by Carnegie Tech grad. (1932). Prefers position with an opportunity for research in the transmission of moving pictures, 8 yr. experience as moving picture operator (present employment). Experienced in taking pictures and developing films. Married, 26. D-1419.

B.S. in E.E., 1932, Mich. Col. of Min. and Tech., married, 23, desires position in any engg. field. Good scholastic record. Tau Beta Pi. Salary and location, immaterial. Available at once. D-1418.

E.E. GRAD., 1932, single, B.S. VPI, prepared to learn and specialize in any line of E.E. work. Excellent character. Little experience in conduit work. Virginia present address. D-1420.

B.E.E., 1932, U. of Minn., 21, single. Two summers constr., Northwestern Bell Tel. Co. Major in communications. Special investigation of microphones. Desires any position. Not afraid of hard work and satisfied with decent living wage. Location, immaterial. Good scholastic record and character references. Good physical condition. Available immediately. D-1425.

1930 GRAD. in E.E., B.S. from North Car. State College, 25, single. 2$^1/_2$ yr. experience in installation of motors and bldg. wiring, 2 yr. with constr. co. in inspecting and testing pwr. transformers and other equip. for substations. Location, East. Available at once. D-1431.

E.E. GRAD., B.S. in E.E., U. of Ill., 1932, 23, single. Ten months long distance telephone test A. T. & T.; 2 months Ill. Bell Tel. Co. Some knowledge of motion picture sound equip. Familiar with vacuum tubes and their applications. Available at once. Location, immaterial. D-1108.

E. E. GRAD., U. of Ill., 1932, single. Fifteen months Westinghouse test. One yr. teaching pub. sch. Desires permanent connection. Available at once. Starting salary and location, immaterial. D-1446.

E.E. GRAD., M.S. in E.E., Iowa St. Col., 1932, 22, single. Best of character and willing to start at the bottom and work up. Short experience in tech. writing. Desires any position that will pay a living wage. Available immediately. D-1276.

E.E. GRAD., B.S. in E.E., Drexel Inst., 1932, cooperative course, 23, single. Nine months in plant dept. of N. J. Bell Tel. Co.; 6 months pwr. plant testing. Desires engg. or teaching position. Location in East preferred. References upon request. Available immediately. D-1466.

E.E. GRAD., U. of Minn., 1930, 25, single. Two yr. experience with Northern States Pwr. Co., including 1 yr. training course and 1 yr. distribution engg. Available immediately. Location, immaterial. D-1477.

E.E. GRAD., 24, single. Broad education and experience, good record; 4 yr. Bell system, 1 yr. elec. mfg. and development. Interested appraisal, aeronautics, air conditioning, refrigerating, utility, mech. engg., or other work. Also experienced secretarial, traffic and chem. mfg. lines. Excellent references. Location and salary, immaterial. D-1475.

JR. ENGR., S.B., 1926 M. I. T., single, 28; 5 yr. experience with large company on design, engg., and constr. on pwr. plants, substation and indoor plants. Desires connection with constr., util., or holding co. Available immediately. D-1487.

B.S. in E.E. CCNY, Tech. high school, 2 yr. radio experience, 21. Desires position as asst., sound, radio work, etc. Moderate salary, references. D-1488.

B.E.E. Northeastern Univ., 1931. Cooperative course, single, 24. Desires position with utility or engg. firm. About 1$^1/_2$ yr. on substation and switching yard work, also some maintenance work. Available at once. B-41.

TECH. WRITER, Cornell A.B. and E.E., 23, single. Special training in writing clear concise English fits him to prepare reports, specifications, instruction sheets, publicity, etc. Experienced in pwr., radio, and communications fields. Salary secondary to opportunity in this particular work. Location, immaterial. Available at once. D-1221.

E.E. GRAD., 1931, cooperative course, 23, single. Broad general experience. One yr. with radio concern, 8 months on registers. Literary ability. Salary immaterial. Location, East preferred. Available immediately. D-1414.

YOUNG ENGR., I.E.E. grad. 1930, desires position in jr. engg. work. Has had 4 yr. varied elec. experience including lt., heat and pwr. wiring and automatic relay (telephone type) equip. maintenance. Aggressive, capable and not afraid of hard work. Salary and location, secondary. D-1465.

RENSSELAER P. I. GRAD., elec. engr., 23, single. Wishes position in any elec. field. Has worked 1 summer with Pub. Serv. of N. J. and 1 summer with G. E. Co. in N. Y. City shop. Available at once. D-1158.

E.E., 21, B.S. in E.E.; 1 yr. experience in elec. motor repair and constr. Interested in elec. pwr. engg. Location, immaterial. Available immediately. D-1485.

E.E. GRAD., Northeastern Univ. 1932, single, 21; 1 yr. transformer testing. Good references. Prefer position with utility, but will consider anything. Salary and location, secondary. Available immediately. D-1498.

GRAD.; E.E. 1929. G. E. test experience including work in radio and vacuum tube engg. depts. and with all types of elec. mchy. Utility elec. rate analysis experience covering pwr. companies in all states. Received M.S. in June 1932. Desires an engg. opportunity. D-1036.

### Maintenance and Operation

CONSTR. AND MAINTENANCE SUPT., 37, married. Grad. E.E.; 13 yr. experience in the utility field, particularly in engg., constr. and maintenance of distribution and transmission substations. Desires position with large utility with responsibility for the constr., operation and maintenance of substations. B-2885.

E.E., grad., 1929, 26, married; 1 yr. Westinghouse grad. student course and 2$^1/_2$ yr. of elec. test. Desires position as maintenance, installation or operating engr. Location, immaterial. Available with 2 weeks notice. C-7431.

E.E., 18 yr. experience on design, construction, maintenance, operating methods and problems, desires position with pwr. co. or firm using elec. driven equip. Univ. grad. B-1923.

### Research

Ph.D. in E.E. Calif. Inst. Tech. '32. 2 yr. practical experience as electrician; 5 yr. elec. drafting, teaching and research. Research dealt with measurement of ltg. currents and especially with elec. dehydration of petroleum. Desires research position where experience and training will be useful. Single, 28. Location, immaterial. D-1350.

E.E. 1930, with 2 yr. research work, post-grad. study and excellent scholastic record, desires tech. work, preferably mathematical. Location, vicinity of N. Y. City preferred. D-1183.

E.E., Brown, 1921; Columbia Univ.; 32, single; 5 yr. Western Elec. Co., installation, test, design, automatic telephone equip.; 6 yr. Bell Telephone lab., design, development, research, electromagnetic relays, vacuum tube circuits for cable and radio. Interested; consulting, development, research on above and allied fields. Languages, French, German. Prefers New York. C-1047.

RESEARCH ENGR., specialties, photoelectric color-matching equip.; light sources. B-7066.

TESTING AND RESEARCH ENGR., Phys. tests of materials, metallography, X-ray and spectroscopic structure analysis. Well versed in physics. Languages: English, German, French. Location and salary of secondary importance to opportunities. C-6994.

DEVELOPMENT ENGR., 26, single, E.E. and M.S., high scholastic rating; 3 yr. G. E. Co. research, test and field engg., 2 yr. development of pwr. plant equip. for telephone offices. Location, immaterial. Best of references. Available now. D-1219.

ENGR., 15 yr. automatic printing telegraph development, including 7 yr. with mfr., desires situation, preferably East. Salary consistent with responsibilities. Broad experience with fine high-speed mchy.; sound knowledge of circuits and circuit theory; can handle men; languages, French, Spanish. Available now. D-1459.

B.S. in E.E., Harvard 1924, G. E. test and 5 yr. in research lab. in Schenectady. Research work involving elec. arcs or switching phenomena preferred, but open for other engg. work. Available immediately. D-1486.

E.E. GRAD., 23, Sc.M. M. I. T., Harvard '28; Sc.D. M. I. T. June '32; single, 38; 9 yr. practical experience pwr., business and communication engg.; 2 yr. testing course. Valuable contribution to net-work synthesis. Speaks Swedish, English, German; reading knowledge French. Desires position, well known organization. Available. Location, immaterial. D-747.

### Sales

SALES ENGR. OR MFG. AGT., grad. E.E., 32. Over 5 yr. with utility in constr. maintenance and design; over 3 yr. as sales engr. for elec. mfr. including about 3 yr. as jr. exec. Location immaterial for salary position. Pittsburgh headquarters as mfg. agent. D-745.

B.S., E.E., U. of Ill., 1930, single; 2 summers A. T. & T. Co. Student engr. 6 months, Elec. Mach. Mfg. Co. Employed since Jan. 1931, special committee, stresses in R.R. tracks, asst. test engr., U. of Ill. Interested, pwr., a-c. mchy. Experience, sales work. Available month's notice. Salary, promotion primary. Location, secondary. D-1439.

DISTRICT SALES MGR. OR MFRS. AGT.: experienced engg. representative, desires connection with high grade co. that has line of industrial or utility equip. Eastern location preferred. B-4067.

B.S. in E.E., PROF. ENGR., N. J., 34, married. Steel corp. sales engr. 3 yr. contacting archts., engrs., N. Y., N. J.; heat and sound insulation sales engr., 4 yr. contacting architects, engrs., heating trade, plus job supervision; storage battery automotive elec. sales and service 5 yr.; inventive ability and experience. C-75.

# Membership

## Applications for Election

Applications have been received at headquarters from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the acting national secretary before Oct. 31, 1932.

Baldwin, J. G., Montreal Lt., Heat & Pwr. Consolidated, Montreal, Quebec, Can.
Basinger, C. B., Wind Turbine Co., West Chester, Pa.
Fetterman, R. E., 340 Wilson Ave., Port Clinton, Ohio.
Fracker, H. E., Bell Tel. Lab., N. Y. City.
Greene, A. B. (Member), Florida R. R. Commission, Tallahassee.
Harris, R. S., c/o Lowell Observatory Flagstaff, Ariz.
Hedrick, W. A. (Member), 422 College Ave., N. E., Grand Rapids, Mich.
Hess, W. F., 25 Hawthorne Ave., Troy, N. Y.
Litchfield, N. (Member), c/o Gibbs & Hill, N. Y. City.
Niedurny, W. J., c/o L. E. Myers Co., N. Y. City.
Pitman, J. B., 3110 Lincoln Ave., Alameda, Calif.
Sine, E. R., Box 226, Nassau, N. Y.
Whalley, R., Pacific Elec. Mfg. Corp., San Francisco, Calif.
13 Domestic

### Foreign

Alizo, C., Antonio Cia. Annma., Planta Elec. de Valera, Est. Trujillo, Venezuela, S. A.
Banton, F. B. (Member), Cia Colombiana de Electricidad, Barranquilla, Colombia, S. A.
Foulsum, W. C., 16 Bondoran Parade, Mont Albert, Melbourne, Australia.
Gibbes, G. B., Govt. Elec. Dept., St. George's, Grenada, B. W. I.
Kesavan, V. K., Pwr. Station Kottayam Travancore, So. India.
Lautier, V., 37, Sda. San Paolo, Cospicua, Malta.
Rozario, J. F. T., Pub. Wks. Dept., Madras Govt., Madras, India.
Sarda, P. M., Ratan Pole, Nagori Pole, Ahmedabad, India.
Singh, H., Simla Municipal Committee, Idgah, Simla.
Swami, T. V., Elec. Dept., Cocanada, India.
10 Foreign

# Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the address as it now appears on the Institute records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Adams, Albert J., 950—18th Ave., Honolulu, T. H.
Bingel, G. H., Gen. Del., City Hall P. O., N. Y. City.
Bohner, C. W., 620—22nd Terrace, Miami, Fla.

# Engineering Literature

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statement made; these are taken from the preface or the text of the book.

All books listed may be consulted in the Engineering Societies Library.

Die ABHÄNGIGKEIT der WERKSTOFF-DÄMPFUNG von der GRÖSSE und GESCHWINDIGKEIT der FORMÄNDERUNG. (Mitteilungen des Wöhler-Instituts, Heft 11.) By E. Bankwitz. Berlin, NEM-Verlag, 1932. 53 p., illus., 8x6 in., paper, 3.60 rm.—On the behavior of metals under repeated stress. Vibration diagrams of steel, copper, brass, and aluminum, based upon careful tests, are given and the influence of speed of deformation upon the magnitude of damping and of alternating stresses upon the static properties of these materials are discussed.

ANNUAIRE des INGÉNIEURS de FRANCE, 1931. Paris, Loubat, Éditeur. 1070 p, 9x5 in., paper, no price given.—A directory including names of engineer graduates of the 12 principal engineering colleges of France, and members of the French Society of Electricians and of the Society of Civil Engineers of France; about 35,000 names and addresses.

ARCHITECTURAL ACOUSTICS. By V. O. Knudsen. New York, John Wiley & Sons, 1932. 617 p., illus., 9x6 in., cloth, $6.50. A reference for architects, builders, and others interested in design and construction of buildings, with theory and practical application of architectural acoustics clearly set forth. Essentially practical in character; it gives information upon the absorption of sound, sound insulation, properties of insulating materials and the acoustics of auditoriums and music rooms. The application of acoustics to schools, churches, theatres, and other buildings is discussed at length and liberally illustrated. A book to enable the architect and builder to meet his problems intelligently.

AVIATION and the AERODROME. By H. A. Lewis-Dale. Philadelphia, J. B. Lippincott Co., 1932. 168 p, illus., 9x6 in., cloth, $6.00.—Dealing with the question of sites and the broad aspects of the engg. problems of a more or less specialized character involved in the construction and ground equipment of aerodromes. The treatment is concise and definite, with numerous examples of plans and buildings. The author, since 1914, has been engaged in the construction of aerodromes for the British Admiralty and Air Ministry.

CARL von LINDE zum 90. GEBURTSTAG. (Deutsches Museum Abhandlungen und Berichte, Jahrgang 4, Heft 3, 1932.) Berlin, VDI-Verlag, 1932. P. 55–84, 8x6 in., paper, 1 rm.—A brief memorial celebrating the 90th birthday of the famous engineer, with an extract from his autobiography, a bibliography of his published writings, an address upon the fixation of gases of the atmosphere and a short historical account of the evolution of refrigeration.

DANA'S TEXTBOOK of MINERALOGY with an extended treatise on crystallography and physical mineralogy. By E. S. Dana. 4th ed. by W. E. Ford. New York, John Wiley & Sons, 1932. 851 p., illus., 9x6 in., cloth, $5.50.—The new edition of this well-known textbook has been brought thoroughly up to date. Essential changes include new sections upon crystal structure and investigation of it by means of X-rays; also upon the origin, mode of occurrence, and association of minerals. The section upon descriptive mineralogy fully revised and description of about 220 new species added. The last section now includes brief descriptions of all known minerals.

ELEKTROLYTE. By H. Falkenhagen. Leipzig, S. Hirzel. 1932, 346 p., illus., 10x7 in., paper, 23 rm.; bound, 24.80 rm.—An able review of the work of Faraday, Arrhenius, Lewis, van Laar, Milner, Debye, and many others who have studied the theory of electrolytes. The evolution of current theories is traced carefully and comprehensively.

Die FERROMAGNETISCHEN LEGIERUNGEN. By W. S. Messkin and A. Kussmann. Berlin, J. Springer, 1932. 418 p., illus., 10x6 in., cloth, 44.50 rm.—This book is a systematic survey of ferromagnetic metals and alloys presenting in a practical way not only the properties from a magnetic point of view, but also the influence of metallurgical treatment upon these properties. Designed to serve the metallurgist, the physicist, or chemist engaged in research work, and the electrical engineer, it opens with the theory of magnetism; then the author discusses magnetic measurements, the influence of chemical composition and physical state upon magnetic properties, magnetic analysis of metals, physical properties, permanent magnet steels, alloys for dynamos and transformers, alloys for special purposes, and the production of magnetic alloys. It is an endeavor to consider all the alloys now used industrially as well as those for prospective use.

HIGHWAY MATERIALS. By E. E. Bauer. 2 ed. New York & London, McGraw-Hill, 1932. 374 p., illus., 9x6 in., cloth, $3.50. Intended primarily as college text, to give the student a general working knowledge of the qualities of materials for various types of pavements. Besides the methods of sampling and testing, qualities and specifications of road materials and the interpretation of the results of tests are discussed. Specifications and tests of the Am. Soc. for Test. Mats. are used, this edition revised to include its latest practise.

NEGRO HOUSING. Edited by J. M. Gries and J. Ford. Washington, D. C., President's Conference on Home Building and Home Ownership, 1932. 282 p., illus., 9x6 in., cloth, $1.00.—A comprehensive, valuable report, based upon a nationwide survey of conditions. The social, economic, and financial phases of the problem are presented. The committee finds a remedy for the negro citizens inability to obtain sanitary dwellings and privacy, by providing housing acceptable to persons of low incomes through better plans of production for all housing.

SCHWINGUNGEN an FREILEITUNGSSEILEN und ihre DÄMPFUNG durch RESONANZ-SCHWINGUNGSDÄMPFER. (Mitteilungen des Wöhler-Instituts, Heft 12.) By F. Puritz. Berlin, NEM-Verlag, 1932. 67 p., illus., 8x6 in., paper, 3.60 rm.—A report giving results of experiments upon methods of reducing vibrations in electric lines and masts. Rubber dampers adjusted to the rate of vibration of the mast-wire system were found helpful.

SCIENTIFIC PRINCIPLES of PETROLEUM TECHNOLOGY. By L. Gurwitsch and H. Moore. 2 ed. New York, D. Van Nostrand Co., 1932. 572 p., illus., 9x6 in., cloth, $8.00.—In 1926 Mr. Moore published a translation of Prof. Gurwitsch's well-known book, with additions. This translation he now has revised and expanded to include especially the results of recent American research work. The book discusses the chemistry and physics of petroleum and principal products and methods of distilling and refining them from the scientific point of view without attempt to treat practical questions of technology. As a review of petroleum chemistry, this work should be a welcome addition to literature.

SMOKE: A Study of Aerial Disperse Systems. By R. Whytlaw-Gray and H. S. Patterson. London, Edward Arnold & Co., 1932. 192 p., illus., 9x6 in., cloth, 14s.—Few attempts have been made to explain the behavior of smoke in terms of general principles, or even to correlate its properties with the number, size, and nature of its constituent particles. This volume delineates the scientific study of smoke, based largely upon the last few years of investigations at Leeds. It provides a general survey of the subject, and describes methods of investigation and results obtained, pointing out further lines of research.

STRESSES in SIMPLE STRUCTURES. By L. C. Urquhart and C. E. O'Rourke. 2 ed. New York and London, McGraw-Hill, 1932. 339 p., 9x6 in., cloth, $3.50.—A textbook to set forth clearly the fundamentals of stress calculation in simple structures, without consideration of economics of design. Both analytical and graphical methods are used. A new edition, entirely rewritten, and with new chapters upon the 3-hinged arch and deflection.

TECHNISCHES WÖRTERBUCH VII (Sammlung Göschen 1050). Die wichtigsten Ausdrücke der Elektro- und Radiotechnik. Pt. 3. Deutsch-Französisch. 2 ed. By E. Krebs. Berlin and Leipzig, 1932. 187 p., 6x4 in., cloth, 2 rm.—A concise German-French dictionary of terms used in radio and telephone engineering, similar to the earlier German-English dictionary by the same author. The volume is of convenient pocket size with words well chosen for ordinary needs.

ZAHNRÄDER, Pt. 1. (Werkstattbücher, Heft 47.) By G. Karrass. Berlin, J. Springer, 1932. 60 p., illus., 9x6 in., paper, 2 rm.—A concise work on the design of gears. One of a series upon shop practise. The aim is to present the subject both scientifically and practically upon the basis of current practise and without complicated mathematics.

HOUSE DESIGN, CONSTRUCTION, AND EQUIPMENT. Edit. by J. M. Gries and J. Ford. Washington, President's Conference on Home Building and Home Ownership, 1932. 325 p., illus., 9x6 in., cloth, $1.00.—The program for raising the standard of American housing adopted December 1931 by the President's Conference on Home Building and Home Ownership has resulted in reports by experts. This one is the work of committees composed of well-known architects, engineers, and home economists from all parts of the country. Recommendations are based upon practical experience and essentials of good practise; also better coordination of effort in the building trade is discussed indicating how building costs may be lowered for the wage-earner. Much useful information for architects, builders, and prospective owners is given.

HYDROGEN IONS. By H. T. S. Britton. 2 ed. N. Y., D. Van Nostrand Co., 1932. 589 p. illus., 9x6 in., cloth, 25s.—An exhaustive, critical summary of present literature upon methods of determining the concentration of hydrogen ions, the importance of these ions in general chemistry, their rôles in industrial processes, and the value of hydrogen-ion concentration measurements for purposes of control. The discussions of the importance of hydrogen-ion concentrations in the electrodeposition of metals, in tanning, sugar manufacture, pulp and paper-making, water purification, corrosion, sewage disposal, ceramics, and flotation will be useful to engineers wishing a concise introduction to modern progress. Thoroughly revised.

## Engineering Societies Library

29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of Engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

# Industrial Notes

**Lincoln Appoints G. E. Tenney.**—Announcement has been made by the Lincoln Electric Company, Cleveland, of the appointment of G. E. Tenney as sales manager of its Chicago district. The Chicago offices are located at 1455 West 37th Street, where a sales and service organization is maintained for all Lincoln products, including "Shield-Arc" welders, welding supplies, and "Linc-Weld" motors.

**Rapid Reversing Motors.**—The Louis Allis Company, Milwaukee, announces a new line of rapid reversing squirrel cage motors, capable of as many as sixty reversals per minute continuously without overheating. Such high rates of reversals have been made practical through lightweight rotor construction, efficient ventilation, high torque characteristics, and shock resisting cast iron frames.

**New Disc Switch.**—The Square D Company, Detroit, has recently developed a new type of disc switch. The new switch has several advantages over standard designs, including front operation, and requires little mounting space. It has a quick make and break action and may be obtained either fused or unfused. Copper switch contacts reinforced by rustless steel springs, insure constant pressure and reduced heating. The switch is rated for either 30 or 60 ampere, single pole, two pole, two wire solid neutral or three wire solid neutral.

**A New Liquid Insulator.**—A new synthetic liquid insulator which has been announced by the General Electric Company not only has the advantages of mineral oil as an insulating and cooling medium for electric equipment but in addition is noninflammable and non-explosive. Designated by the trade name Pyranol, the material is produced in different forms for different purposes. For economic reasons, mineral oil will probably remain in general use for years, according to General Electric engineers at Pittsfield, Mass., but commercial installations of Pyranol indicate numerous applications where the new material is especially valuable. Capacitors can be made physically smaller per microfarad, with increased reliability; and the higher cost of transformers with Pyranol is justified when the equipment must be completely proof against fire and explosion hazards. Since the liquid is a solvent for some materials ordinarily used in electric equipment, particularly transformers, the apparatus must be designed specially for its use. Its dielectric constant (specific inductive capacity) is practically that of solid insulations, and its dielectric strength is of the same high order as that of mineral oil.

The liquid is chemically stable and it resists oxidation, so that there is no sludging after continued exposure to heat or air. It demulsifies, or separates from water, more than twice as rapidly as does mineral oil, and the moisture rises to the surface from which it may be evaporated. Viscosity and freezing point can be varied to suit conditions without affecting other qualities of the liquid. When Pyranol is subjected to an electric arc, the principal product is hydrogen chloride, an irritating but not actively poisonous gas which can be removed by an absorption device or piped to the open air for dissipation.

# Trade Literature

**Lightning Arresters.**—Bulletin 14325, 8 pp. Describes valve type lightning arresters. Line Material Co., So. Milwaukee, Wis.

**Arc Welder.**—Bulletin, 8 pp. Describes the new Lincoln "Shield-Arc" welder. The Lincoln Electric Co., Coit Rd. and Kirby Ave., Cleveland, O.

**Resistance Standards.**—Bulletin 100, 6 pp. Describes resistance standards and resistance measuring devices. Rubicon Co., 29 North 6th St., Philadelphia, Pa.

**Carbon Brushes.**—Catalog 13, 24 pp. Describes carbon brushes for single phase and other fractional horsepower motors. Boxill-Bruel Carbon Co., Columbia Park, O.

**Air-Break Switches.**—Bulletin 9324, 4 pp. Describes gang operated air-break switches for low cost construction. Line Material Co., Milwaukee, Wis.

**Electric Equipment for Mine Hoists.**—Bulletin GEA 1593, 24 pp. This bulletin is descriptive of General Electric practise and accomplishments in mine-hoist service in both coal and metal mining. General Electric Co., Schenectady, N. Y.

**Stainless Steel Tubing.**—Bulletin. Describes Carpenter stainless welded tube made from cold rolled stainless strip steel. Both the inside and outside surfaces of the tube represent surface metal from the original ingot. The Carpenter Steel Co., Welded Alloy Tube Div., 100 Broadway, New York.

**Smoke Density Meter.**—Bulletin. Describes the Brown smoke density meter which has been under development for a number of years, for recording and measuring the quantity or the color of smoke emission. The Brown Instrument Co., Wayne & Windrim Sts., Philadelphia, Pa.

**Water Softeners.**—Bulletin, 36 pp. The application of Zeolite water softeners to the treatment of boiler feed water is outlined; profusely illustrated with photographs and diagrams, and contains tabulated data, conversion tables, factors, reactions, etc. The Permutit Co., 440 Fourth Ave., New York.

**Rubber Paints.**—Bulletin, "Acidseal Paints." Describes a recently developed line of rubber paints. These paints have as a base a commercial form of rubber isomer, and retain the elastic properties of rubber, conforming to the expansion and contraction of the surface covered, and minimize the corrosive action of acids, alkalies, and chemical fumes. The B. F. Goodrich Co., Akron, O.

**Industrial Lighting Equipment.**—Catalog 219-A, 64 pp. This new catalog describes each unit plainly and lists them in a manner easy to find. A complete line of equipment is covered including new units, low priced industrial floodlights and quick change Wemco reflectors and sockets. Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

**Industrial Scales.**—Bulletin, 8 pp. Describes the improved line of Kron automatic industrial scales. Included are dial track scales, portable pan, portable platform, dormant platform, bench, hopper, crane, and pitless suspension types. All have been completely redesigned and the dial and lever mechanism considerably simplified. The Kron Co., Bridgeport, Conn.

**Circuit Breakers.**—Bulletin 1771-B, 8 pp. Describes manually and electrically operated oil circuit breakers, 7,500 and 15,000 volts, especially suitable for indoor power house use where space is restricted. De-ion grids have been used in some of the units. Bulletin 1958, 12 pp., describes another range of De-ion grid oil circuit breakers for indoor service in voltages from 15,000 to 34,500 and interrupting capacities from 500,000 to 2,500,000 kva. Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

**Propeller Turbines.**—Bulletin 38, 8 pp. Describes I. P. Morris propeller turbines having adjustable blades and fixed gates. These turbines are intended primarily for low heads and are designed to supply an efficient unit at a price lower than the price of the adjustable gate-adjustable blade propeller turbines with their two complete sets of control equipment. They are particularly indicated where the revamping of existing and less efficient plants is in contemplation. The bulletin includes power-efficiency curves, line drawings of the turbines and a "Chart of Characteristics for Standard Turbines" in two colors. Baldwin-Southwark Corp., I. P. Morris Div., Philadelphia, Pa.

**Meter Test Block.**—Bulletin CA-25, 8 pp. Describes a new type of plug-in meter test block, which permits easy connection and removal of the meter. The new block does away with meter loops and cross-overs in the meter connections. All cross-overs are provided in the base of the new block and the meter terminal connections slide down over semi-rigid connectors. Furthermore, unsightly wiring is eliminated, time is saved in installing or removing meters, and the meter links can be separately inserted or removed without disturbing the meter or base. The wiring order is the same as employed in ordinary test blocks and testing is accomplished with standard links, which are supplied. The block is built in indoor and outdoor meter cabinets. Switch and Panel Division, Square D Co., Detroit, Mich.

**Officers and Committees** (For complete listing see p. 678–81, September 1932 issue of ELECTRICAL ENGINEERING.)

MEMBERS of the Institute continue to make use of "Letters to the Editor" columns for the open-forum expression of their varied ideas on many subjects. *p. 813–15*

WHETHER OR NOT engineering progress benefits mankind depends upon how it is used, according to the fourteenth article in the Engineering Foundation's symposium "Has Man Benefited by Engineering Progress?" *p. 794–5*

IN THE FIRST 6 months of operation "not a single train delay has been caused by failure of the supervisory control equipment." Such is the report on the suburban electrification of an eastern railroad, all substations and switching stations of which are equipped with supervisory control. *p. 776–8*

BY DEPARTING from the conventional circular cross-section in cables used for transmitting electric power on overhead lines, the tendency of the cables to vibrate can be reduced; of several specimens tested, those having a triangular cross-section show least tendency to vibrate. *p. 795–8*

FROM an engineering study of the voltage and current wave forms of neon tubing commonly used for sign lighting, an explanation of its physical operation has been developed. *p. 772–5*

ENGINEERS have begun to plan for the relief of their unemployed during the coming winter. It is estimated that this year's needs will at least equal those of last year. *p. 809–13*

ALTHOUGH the thin oxid film with which aluminum protects itself from corrosion has been studied a great deal, only comparatively recently have thicker films produced "artificially" received much attention. These thicker films possess interesting properties and lend themselves to a variety of uses. *p. 778–80*

PEAKED voltage waves as narrow as 2 electrical degrees now can be obtained direct from a sinusoidal voltage source by the use of a specially designed transformer. *p. 802–4*

DEMAND for a simple and nondestructive method of testing finished welds has been met by an a-c bridge method with a visual balance indicator. Such a device is described in the A.I.E.E. 1931 national prize Branch paper. *p. 781–3*

PLANS for the A.I.E.E. 1933 winter convention already are assuming definite form. A general convention committee recently was appointed by President Charlesworth, and already has begun to arrange for the various events. *p. 807*

PREVIOUSLY published analyses of synchronous motor performance have been extended; from known formulas for the 3-phase short-circuit torque, expressions have been derived by which the torque from a single-phase short-circuit can be determined. *p. 799–801*

REGAINING stability in an electric power system is quite as important as maintaining it. To determine the proper operating procedure for quickly regaining synchronism once the system is out-of-step, an actual out-of-step condition on a large Pacific Coast system was exhaustively analyzed. *p. 769–72*

PROGRESS in insulation during the past year, both in theory and application, has been summarized in a report to the committee on electrical insulation of the National Research Council presented at the fifth annual meeting of the committee by its chairman, Dr. John B. Whitehead (F'12). *p. 765–8*

REGISTRATION at the recent A.I.E.E. district meeting at Baltimore totaled 240, attesting to the general interest value of the technical sessions as did the quality and quantity of discussions presented. Meetings of the Institute's board of directors, District 2 executive committee, and power generation committee, were held. *p. 805–8*

EVEN IN TIMES of low copper cost carrier communication has proved to be an economical means of conveying both telephonic and telegraphic information. A 10-channel 4-wire carrier telegraph system is capable of handling 3,360 words per min. *p. 784–9.* To lessen the labor involved in designing the shaping networks of this system, a direct method of solving coupled tuned circuits was developed. *p. 789–94*

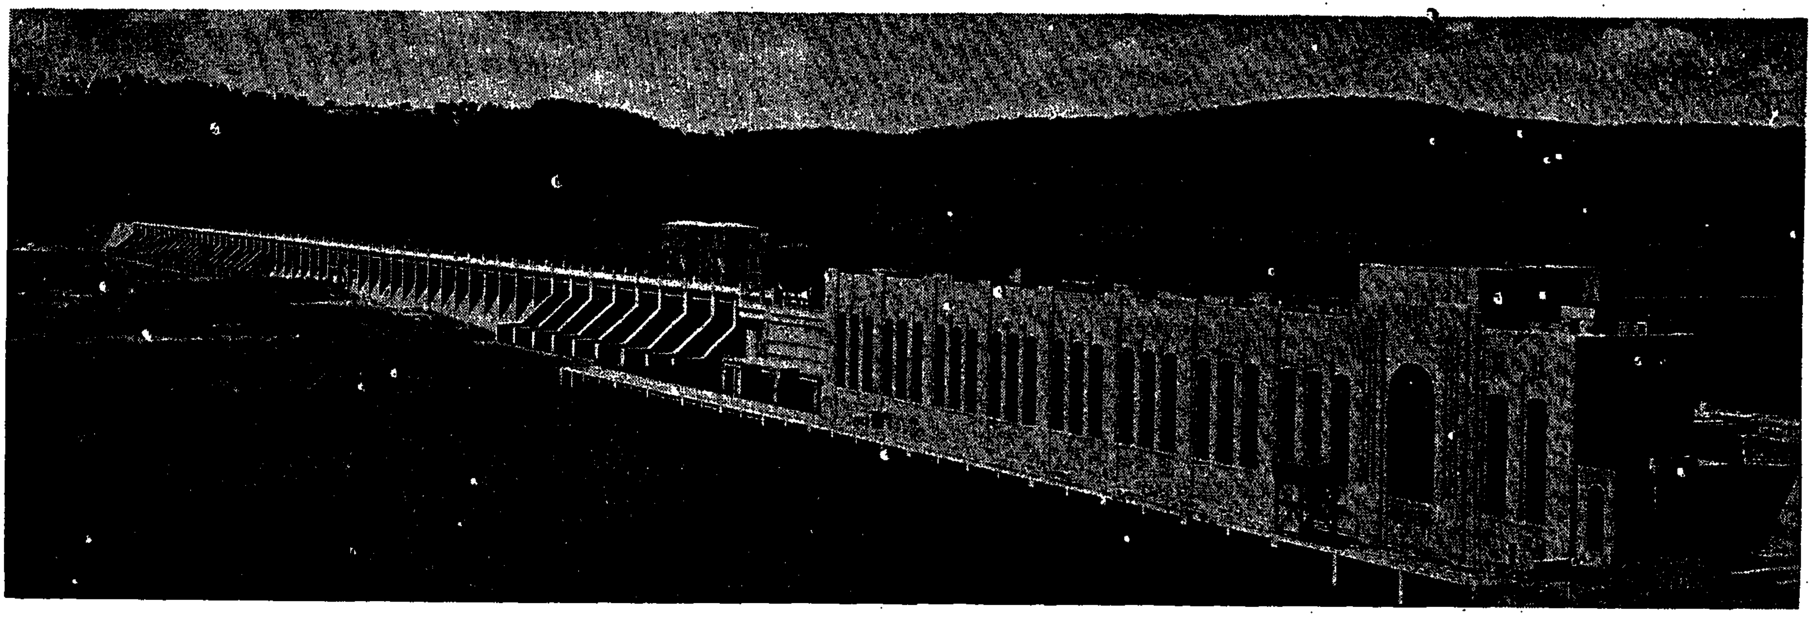

Fig. 1. General view of Safe Harbor plant and dam

# The Safe Harbor Hydroelectric Development

**At Safe Harbor, Pa., has been built the third major hydroelectric plant on the lower reaches of the Susquehanna river. With an ultimate installed capacity of 510,000 hp in turbines, it is destined to become one of the largest hydroelectric developments in the United States. Turbines are of the propeller type with automatically adjustable blades; they are said to be the most powerful of this type ever built. Many interesting details of the development are revealed in this article.**

By
N. B. HIGGINS
MEMBER A.I.E.E.

Safe Harbor Water Pwr. Corp., Baltimore, Md.

WHEN COMPLETED, the Safe Harbor plant will be one of the largest hydroelectric plants in the United States; initial development will include 6 generating units, which in an average year with full utilization will have an output of over 800,000,000 kwhr. The plant is situated along the Susquehanna river a few miles south of Columbia, Pa., and about 1,100 ft upstream from the mouth of Conestoga creek. The development ultimately will have an installed capacity of 510,000 hp in 12 Kaplan turbines, each of 42,500-hp capacity, operating at a speed of 109.1 rpm under a head of 55 ft. Ten of these turbines will drive 36,000-kva 60-cycle 3-phase, 80 to 100 per cent power factor, 13,800-volt generators; and 2 will drive 37,500-kva 25-cycle single-phase, 80 per cent power factor, 13,300-volt generators. Included also in the ultimate plan are 4 25/60-cycle frequency changers of the outdoor type, the generating ends of which will be rated at 31,250 kva, 80 per cent power factor, 300 rpm, 13,300 volts.

Initial development includes 5 60-cycle units, one 25-cycle unit, and one frequency changer; 4 60-cycle units are now in operation, and it is expected that another 60-cycle unit, one 25-cycle unit, and a frequency changer will be installed before the end of 1933.

A major problem in electrical design at Safe Harbor has been to produce a flexible layout, which will permit the installation as required of equipment for generating, transforming, and transmitting 60-cycle 3-phase, and 25-cycle single-phase energy. All generating equipment and the 60-cycle low-voltage bus are located in the power house; all 60-cycle transformers are of the outdoor type, and are located adjacent to the power house. A combined 69-kv and 230-kv 60-cycle substation ultimately will be built on the top of the hill, directly east of the power house. The frequency changers, 25-cycle low voltage bus, and 132-kv 25-cycle step-up substation will be located east of the power house.

One 230-kv circuit has been constructed between Safe Harbor and the Westport station of the Con-

---

Based upon "Safe Harbor Project" (No. 32-123) presented at the A.I.E.E. Middle Eastern District meeting, Baltimore, Md., Oct. 10–13, 1932.

solidated Gas Electric Light and Power Company in Baltimore, Md., and another will be constructed within the next few years, over a separate right-of-way entering the city from the east. A 69-kv double-circuit transmission line, about one mile in length, has been constructed to tie Safe Harbor into the existing 69-kv system of the Pennsylvania Water and Power Company.

The power house is in line with, and forms a continuation of the dam. The substructure is of reinforced concrete, and the superstructure of brick and tile. The total combined length of the concrete dam and power house is 5,000 ft, made up as follows: power house, 916 ft; bulkhead and abutments, 2,274 ft; spillway, 1,810 ft. The entire spillway is equipped with crest gates. General arrangement of structures is shown in Fig. 2.

In extent of drainage basin, and in total and average runoff, the Susquehanna river is the largest river flowing into the North Atlantic ocean, with the exception of the St. Lawrence. Its watershed includes 27,400 sq miles in the states of New York, Pennsylvania, and Maryland. Yet, in spite of this vast tributary area, the stream itself is of little use in commerce; there is practically no navigation above the tide-water limit, which extends only 5 or 6 miles upstream from the mouth of the river.

From Columbia to Tidewater, a distance of 39 miles, the river is walled in by steep bluffs or hills, and the main channel varies in width from a few hundred yards to almost 2 miles. Because of these conditions there has been no industrial development, other than transportation, in this reach of the river. These conditions of rapid descent, steep banks, and the absence of populous towns in a region close to large industrial centers, made this part of the river attractive from a power development standpoint.

Backwater from the dam extends 10 miles upstream forming a lake varying in width from 0.4 mile to almost 2 miles, covering an area of 10.5 sq miles. The water stored in the top foot of the pond is approximately 310 million cu ft; total useful storage is about 3 billion cu ft.

On the east side of the river, 8.5 miles of the Columbia & Port Deposit branch of the Pennsylvania Railroad had to be raised, and on the west side some highway relocation was required; otherwise, improvements effected within the reservoir limits were negligible.

HYDRAULIC STRUCTURES

It was desired to obtain full control of the forebay level for all possible river flows and to maintain constantly the maximum permissible forebay elevation, except when lowering would be desirable to make use of storage. This required a spillway that could be controlled with crest gates for its full length, and capable of discharging the greatest flood assumed possible at the given forebay elevation of 225 ft. Several comparative estimates were made to determine the most economical combination of size and number of gates to produce these discharges. The final analysis resulted in selecting 32 gates for openings 35 ft high and 48 ft wide; tops of gates are 5 ft above initial normal pond level to prevent excessive loss of water from wind action.

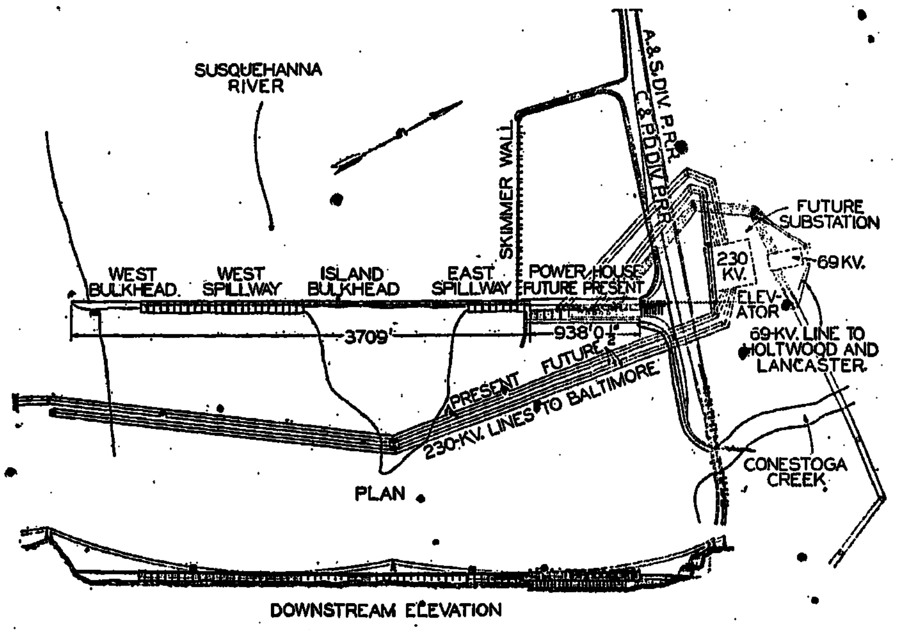

Fig. 2. General layout of structures

At normal forebay level each flood gate will discharge about 30,000 cfs; the west spillway, where 24 of the 32 gates are situated, thus has a discharge capacity of 720,000 cfs, which is equal to the maximum flood of record.

Bulkhead sections are conventional gravity structures; they are designed for compression over the entire foundation joint for headwater at el 228, 10,000 lb per lineal foot of ice pressure at the same elevation, and uplift corresponding to full head at the heel decreasing to tailwater head at the toe following a gradient determined by the foundation drainage system. Design of the spillway is based upon the same assumptions, except that ice pressure there was reduced to 4,000 lb per lineal foot, acting on the gates and transmitted to piers. The lower assumption was considered justified because a compressed air bubbler system has been incorporated in the design to prevent ice pressure from acting on the gates.

The spillway has an overhung crest and a large bucket type of apron; otherwise, it is of the usual ogee cross-section. Shapes of the apron, spillway nappe, and pier noses, were determined by model tests in the Alden laboratory of the Worcester Polytechnic Institute. The dam stands on a sound rock foundation of quartz, mica schist, and phyllite. Because of the excellent quality of the foundation, the strike of the folds, and the dips of the stratum, no cutoff trench was required; natural conditions made it possible, in effect, to obtain cutoff trench advantages at little additional cost. Rock was removed by blasting operations, the average depth of excavation being 11 ft.

Crest gate equipment consists of 28 single-leaf Stoney flood gates, and 4 double-leaf regulating gates, the lower leaf of which is a Stoney gate and the upper leaf a fixed roller gate; there are also 2 emergency gates with fixed rollers. The upper leaves of the 4 regulating gates are operated normally by lowering them and discharging water over the top. By means of these gates, close regulation of pond level can be maintained, and floating debris and ice can be removed easily with a minimum waste of water.

Débris and ice usually will accumulate along the skimmer wall, for which reason the 4 regulating gates are located adjacent to the power house. Upper leaves of the regulating gates are operated by individual hoists located in a tunnel in the body of the dam directly under each gate. Hoist motors for the regulating gates have operating controls at the hoists and also in the power house switch room.

All crest gate equipment is handled by 2 gantry cranes of 150-ton capacity each. These cranes are served from a trolley bus on the operating bridge; in addition, one of the cranes is equipped also with a gasoline engine-generator set for emergency operation.

It is believed that every reasonable precaution has been taken to insure the safe operation of the crest gate equipment under the most unfavorable combination of circumstances. The following features are noted:

1. Large excess capacity of the gantry cranes.
2. One crane can handle gates with sufficient rapidity to meet any normal condition; 2 cranes are provided.
3. Different sources of power for the gantries.
4. Equipment to heat electrically the roller tracks and seal plates on the gate guides.
5. A compressed air bubbling system to prevent ice formation on the upstream side of the gates.

Flood gates are of the usual design of horizontal fabricated girders supporting a skin plate through vertical intermediate beams. The respective weights are 86 tons each for the flood gates (excluding roller trains), and 100 tons each (including fixed wheels) for the emergency gates.

## Power House

Site selected for the power house is in the low-water channel of the river near the Lancaster county shore; minimum excavation for power house and tailrace was an important consideration in the selection of this site. The ultimate length of the power house will be 916 ft; the initial section is 642 ft long, with space for 7 main generating units. A railroad connection extends directly into the generator room assembly bay.

Physical dimensions of the Safe Harbor turbines are the largest for this type of unit so far installed in this country. The maximum scroll case and draft tube width is 55 ft; thickness of piers between units is 7 ft, making the unit spacing 62 ft. Below the water line all contraction joints are sealed with crimped sealing strips made of 24-oz copper, while construction joints between lifts of concrete are sealed with flat copper strips.

Offsetting by 2.5 ft the transverse center line of units with the transverse center line of the intakes presented some difficulty in lining up the piers between waterways; this was overcome by slightly tilting the upper part of the draft tube. Characteristics of the turbines selected required a deep draft tube, but the influence of this on volume of tailrace excavation was reduced by sloping the bottom of the outflow end of the tube upward at the steepest permissible angle without affecting the draft tube efficiency. From low point to exit the draft tube is divided into two equal outlets by a 5-ft pier. For unwatering, the tube can be sealed by a set of sliding gates which are handled by a 25-ton gantry crane from a bridge over the tubes.

From the draft tube outlets the tailrace floor slopes upward to intersect the natural river bed at an angle of 6°. The maximum depth of rock excavation was about 40 ft, 180,000 cu yd of solid rock being excavated to form the tailrace channel. This excavation is the total for the ultimate plant; likewise, the substructure was excavated for all future units.

Intake portion of the power house substructure for the 5 future units was completed, excepting that no intake gate hoists or screens were installed. Intake gates for future units were an important part of the scheme for the control and discharge of the river flow during closure of the last cofferdam.

Floors of the intakes are level at approximately the same elevation as the floor of the forebay; each in-

take consists of 3 water passages, with smooth sloping bell mouths. The cross-section of the water passages at the head-gates measures 15 ft 8 in. wide by 29 ft $4^1/_2$ in. high. Each water passage is controlled by one intake gate; slots are provided in the head works in front of head-gates for the placing of emergency gates when head-gates are taken out of service. Velocities through the gross area of the intake cross-sections vary from 3.32 ft per sec at entry to 7.25 ft per sec at the scroll case intake.

The center gate of each intake travels on fixed rollers, and is operated by a motor-driven screw hoist; the 2 outside gates are sliding gates, and are handled by a 50-ton intake gantry crane, of which 2 are provided. The screw-hoist-operated gate can be raised or lowered under full unbalanced water pressure. The sliding gates are designed to be handled under balanced water pressure only. Emergency valves are provided in the sliding gates for filling the intakes in the event of screw hoist motor failure. The omission of hoisting mechanism on $^2/_3$ of all head-gates resulted in a substantial saving in cost, and does not slow up the starting operation appreciably as a unit can be started with the center gate alone open. Emergency gates are similar to the sliding head-gates and are handled in the same manner.

Intake screens are of welded construction throughout. A single intake screen is made up of 5 vertical sections 12 ft high by 18 ft wide, and slides in slots similar to the gate slots. The face of the screen has a batter of 1 in 24. Individual screen bars and their supporting frame are designed for an unbalanced head of 15 ft of water. Screen bars and supports of streamline shapes were designed to offer a minimum resistance in the water passages. In addition to reducing the loss of head, a flow free of eddies will decrease the tendency for frazil ice to adhere to the screens.

There is provision for a mechanical trash rake, but the rake will be installed only if found necessary. Surface trash and ice that may collect at the turbine intakes can be discharged directly over the screens into the trash sluice built into the substructure. The crest elevation of the sluice is one foot below normal forebay level, and is closed off from the forebay by gates; these gates when raised permit the discharge of all floating debris into the sluice, from where it is carried directly to the tailrace. Compressed air can be discharged at points on the periphery of the intakes to dislodge and float waterlogged debris.

In addition to providing for heating the screens electrically, should this prove necessary, another means to reduce or eliminate ice troubles in the intakes is a provision to discharge the air from the exhaust duct tunnel of the power house ventilating systems, into the space over the screens and below the intake deck.

## Arrangement of Electrical Structures

The electrical bay of the power house, as may be seen from Fig. 4, is between the generator room and the intake structures. It consists of 3 floors housing switching equipment. The lowest floor is occupied by the 2 buses and their taps; the second floor houses oil circuit breakers and disconnecting switches; the third contains potential transformers and reactors. A vertical reinforced concrete fire wall separates the 2 buses and their associated switching equipment. Crosses are made only at those points where taps are taken off to machines, and special attention has been paid to making these vapor-tight.

Above the electrical bay are the transformer pockets, each approximately 40 x 30 ft in size and separated by vertical fire walls one foot thick. Below each transformer is a basin, drained to the tailrace and of sufficient size to accommodate all of the oil in the transformer tank.

The takeoff structure supporting the isolating transformer disconnectors, the lightning arrester disconnectors, and outgoing lines across the forebay are directly above the transformers. Safe and quick maintenance on all switching equipment on this structure is made possible by a complete system of access ladders and working platforms.

In the center of the station a space 165 ft long above the electrical bay is devoted to the control and terminal rooms, batteries, station service transformers, and station service switchboards.

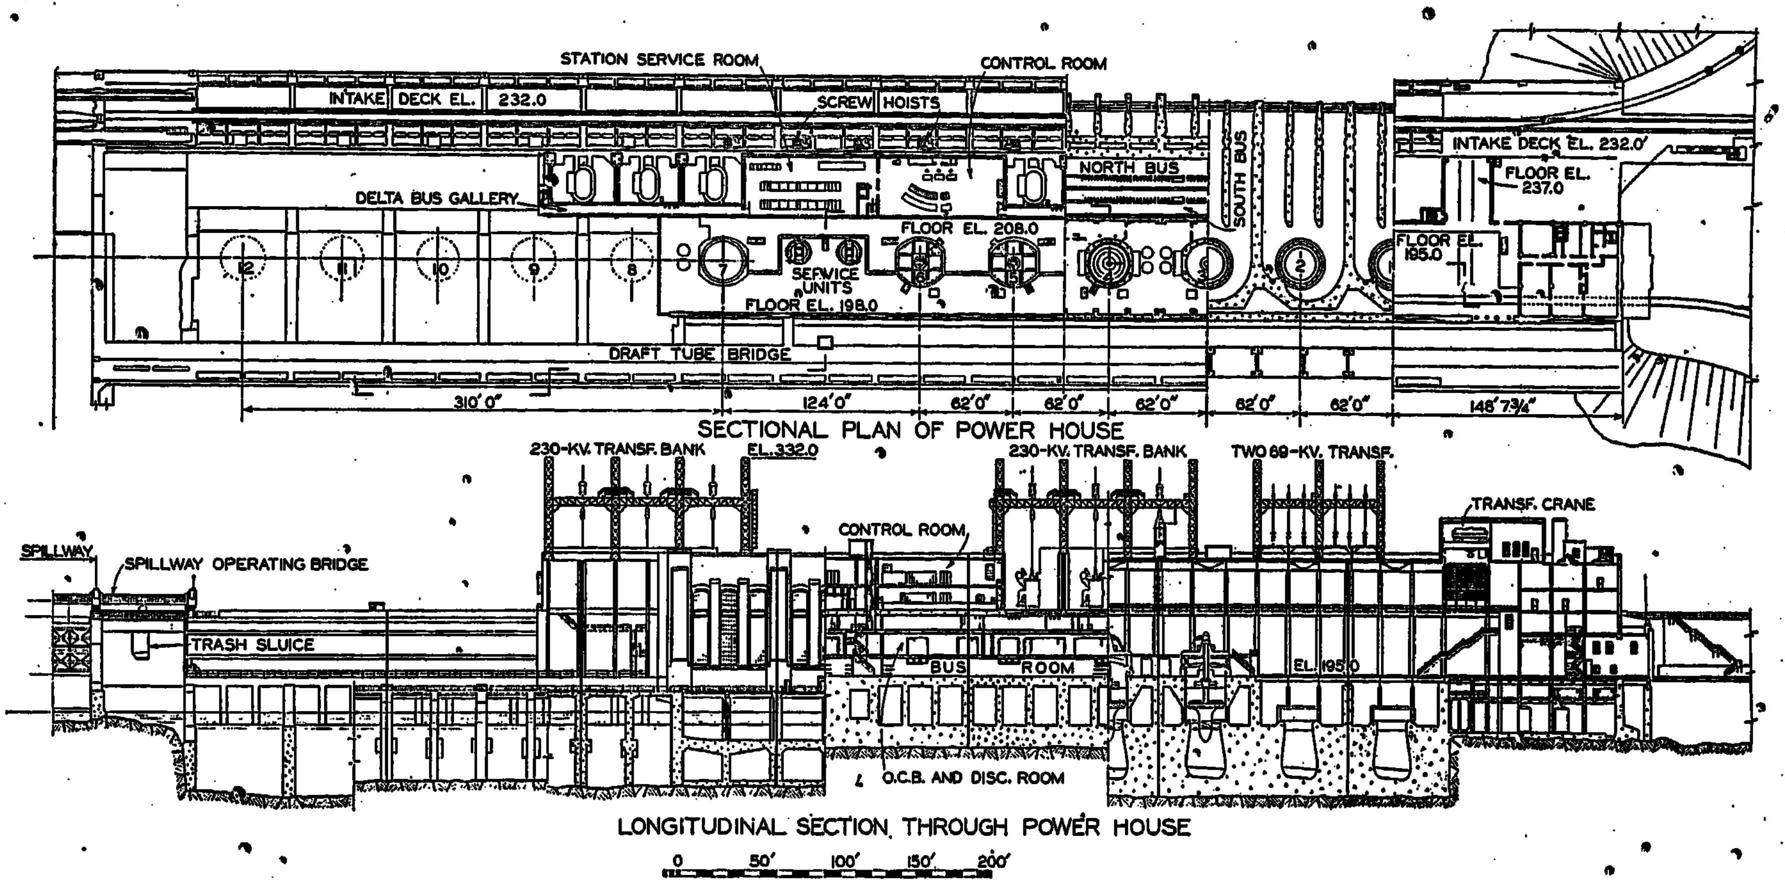

**Fig. 5. Sectional plans and elevations of the power house**

### 60-Cycle Generating System

The 60-cycle generators, of which 4 now are installed, are 3-phase machines, each rated at 36,000 kva, 80 to 100 per cent power factor, 13,800 volts, at 80 deg C temperature rise in both armature and field. As may be seen from Fig. 6, these generators feed into a double bus system which ultimately will consist of 8 sections with 4 sections per bus. The bus and its connected equipment are designed to operate ungrounded; therefore the generator neutrals have been grounded only through potential transformers to which ground indicators are connected. From this bus power is supplied to the 230-kv and 69-kv step-up transformer banks of which ultimately 3 each will be installed. Equipment is connected to the bus by selector oil circuit breakers. Reactors will be installed as needed to hold the short circuit values below 1,500,000 kva.

Only the simplest high voltage switching is provided at the power house. This consists of a motor-driven isolating disconnect with ground switches for each transformer. Lightning arresters, spill gaps, and the lightning arrester disconnecting switches for protecting the transformers also are located at the power house, one set being connected to the outgoing leads of each transformer. At the present time there is no high-tension bus, each transformer bank being connected directly to a transmission line. Either or both of the 2 230-kv transformer banks can be tied to the single 230-kv Baltimore circuit.

The generators are of the overhung rotor type (see Fig. 7) with water-cooled guide and thrust bearings combined in a single housing below the rotor. Guide and the thrust bearings are of the adjustable segmental shoe type; the thrust bearing is designed to carry a total weight of 1,500,000 lb, including a water thrust of 1,100,000 lb. These machines are designed to withstand overspeed to 231 per cent of normal, which value, like that of the water thrust, is somewhat greater than usual on account of the characteristics of the Kaplan turbines.

Diameter of the generators is 29 ft 2 in. and the height 29 ft measured from the lower face of the coupling to the top of the Kaplan head. The weight of a complete machine is approximately 400 tons.

Manufacturers of the generators cooperated in the design of the machines in order to make parts interchangeable as far as possible; those parts exposed in the generator room are identical in appearance.

Class B material is used throughout for insulating the generators. While it is not believed that machines of this size and importance should be operated continuously at the 80 deg C temperature rise, it was decided that excitation should be provided to permit development of the rating corresponding to this rise for use during peaks or emergencies. Normal operation at approximately 28,000 kw, 90 per cent power factor falls within the 60 deg C temperature rise in both armature and field, a rise generally accepted as conservative design practise for this class of insulating material.

A closed system of recirculating air is employed for cooling the generators. Air is introduced below the rotor and is forced by fans attached to the rotor through the windings into an eccentric frame, which serves as a duct to collect and conduct the hot air to the surface air coolers located on diametrically opposite sides of the machines (see Fig. 7). A gravity system of water supplied from the forebay serves the coolers. The air path is totally enclosed throughout; the ducts are equipped with louvres which may be opened as required to bleed air for heating the generator room. The closed system of ventilation was selected rather than open ventilation for the following reasons: reduction in space; better control of generator temperatures; better fire fighting possibilities, and the exclusion of foreign material (particularly construction dirt).

## OIL CIRCUIT BREAKERS AND DISCONNECTS

Oil circuit breakers are insulated for 25 kv and are designed to interrupt successfully 1,500,000 kva at 13.8 kv. They are cell mounted with each tank in an individual concrete cell. Generator and 69-kv transformer breakers are rated at 2,000 amperes, and have normal speed of operation. The 230-kv transformer breakers are rated at 3,000 amperes (2 are used in parallel) and have a guaranteed opening time of 8 cycles from application of tripping current to clearing of arc. Bus tie and bus section breakers are rated 4,000 amperes, and are designed to open at normal speed.

All circuit breakers are interlocked mechanically with their isolating disconnectors. Interlocking is effected further throughout high voltage electrical areas, where the Cory system is used to lock switches and bus doors on 13.8 kv, and switches on 69 and 230 kv. Special precautions were taken to isolate the oil circuit breakers; they are in separate rooms with, in general, not more than 4 breakers in a room. Carbon dioxide fire protection is provided for these rooms, and oil sumps below each breaker tank are drained to the tailrace.

Disconnecting switches isolating the oil circuit breakers are designed so that the 6 poles are operated by one mechanism. When in the open position they are swung into ground clamps, thus isolating and grounding the breaker. All disconnecting switches are mounted on insulators interchangeable with those supporting the bus runs and taps.

## 230-KV TRANSFORMERS

The 230-kv transformers are of the combined gas filled-conservator type in which a 16-in. nitrogen filled space, directly below the cover, is kept under positive pressure by the head of oil in a standard conservator. Expansion and contraction is taken care of by variation of the conservator oil level. They may be operated as standard conservator transformers, if desired.

At present 2 230-kv transformer banks have been installed. Each bank has a normal capacity of 84,000 kva when operating self-cooled, and 126,000 kva with blowers in operation. One bank only is now complete with blowers; blowers are omitted on the second bank because at present it is used only as an emergency spare bank.

The 3 single-phase units comprising each bank are in individual cells; they are Y-connected on the 230-kv side and Δ-connected on the 13.8-kv side. The high voltage neutral is solidly grounded, but the installation is such that the banks may be grounded later through an impedor of such size as will hold the transformer neutral voltage below 76 kv. Four 2½-per cent taps are provided in the high tension winding, 2 above, and 2 below 230 kv. The transformers are insulated to withstand an induced test of 461 kv. Their windings and bushings are designed to be coordinated with each other and with a 46-in. protective gap on the high-tension structure adjacent to the transformers. Each transformer is protected by a thyrite lightning arrester mounted on the power house roof adjacent to the transformers.

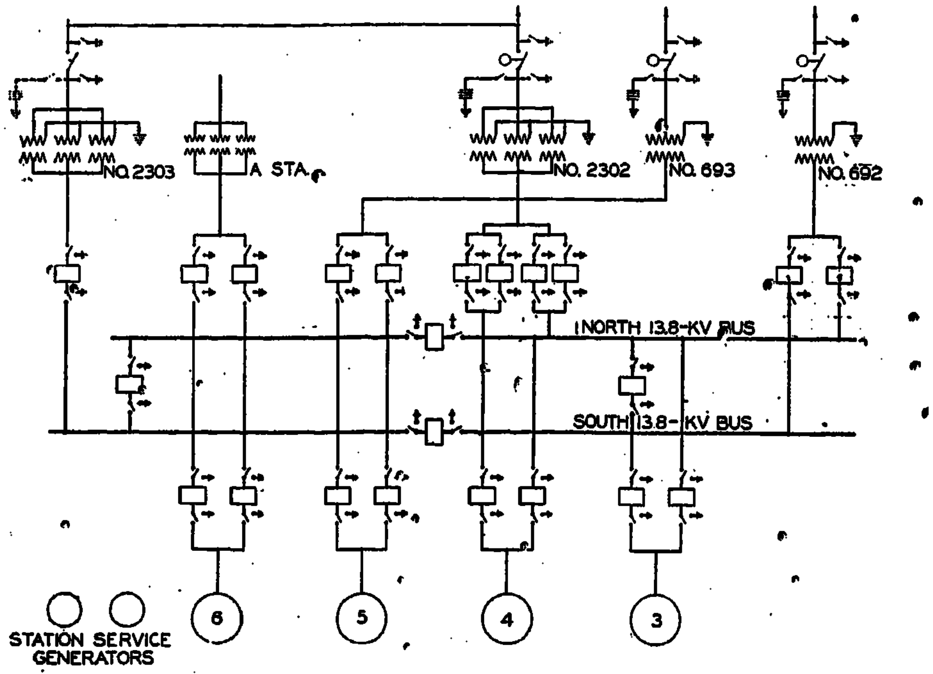

**Fig. 6. Single-line diagram of the 60-cycle system**

Note that each main transformer is connected directly to a transmission line

In addition to the 230-kv transformers, 2 69-kv transformer banks have been installed; these are 3-phase 30,000-kva self-cooled banks of the inertaire type, equipped with blowers to increase this rating to 45,000 kva. They are equipped for tap changing under load over a range of 10 per cent above and below 66 kv. Each transformer is protected by an autovalve lightning arrester mounted on the roof close to the transformer leads; protective gaps are not used at this voltage.

## AUXILIARY POWER SUPPLY

Major auxiliaries at Safe Harbor are supplied at 460 volts from 2 2,500-kva, 70 per cent power factor, house generators, and a single-phase transformer bank of 2,500 kva capacity connected to the main 13.8-kv bus. The house generators are of the umbrella type, and are driven at 180 rpm by 3,100-hp Francis turbines.

There are 2 station buses, each of 2 sections, complete with section switches and one bus tie switch. Positions are available for connecting each of the house generators and the transformer banks to either bus; normally one house unit is connected to each bus. These buses are isolated from each other, each being contained in a steel structure and the 2 separated by a 7-ft aisle. Generators, transformer, and tie and section circuit breakers are of 4,000-amp capacity. All feeder breakers are of the truck type.

## EXCITATION SYSTEM

The unit system of excitation has been adopted, supplemented by a motor-driven spare exciter supplied from the station auxiliary system. Each of the main generators receives excitation from a 185-kw 250-volt main exciter and pilot exciter, both mounted above and direct-connected to its generator, Provision is made for the future addition of a second spare exciter, if found necessary.

Generator main field rheostats are not required, as the generator voltage is controlled by varying the fields of the main exciters. The excitation system is designed for a moderately high rate of response of the order of 100 volts per second. Parallel fields on the main exciter are used to produce that response. An auxiliary field, in which the excitation may be reversed as desired, is provided in each exciter to take care of sudden major changes in voltage. The excitation of each unit is controlled by a high-speed voltage regulator.

## CONTROL

In this station 250-volt control is employed. Duplicate batteries, each with an 8-hr discharge rate of 95 amp to 1.75 volts per cell, are provided. These are equipped with a tap to permit their use for 250/-125-volt auxiliary lighting. Normally, one battery is used for control, the other for emergency lighting and other miscellaneous d-c requirements.

Switching and control for batteries and chargers, and switches for d-c distribution are housed in a dead front steel switchboard. D-c distribution at the main switchboard is handled from duplicate control buses through dead front disconnecting fuses housed in distribution cabinets.

## MAIN GROUND SYSTEM

The island in the middle of the river offered an excellent location for ground electrodes, but it was a considerable distance from the power house. However, 4 ground mats, each consisting of approximately 20 rods connected to 2 500,000-cir-mil cables by a network of 4/0 cable, were located on this island; single lengths of 500,000-cir-mil cable, 300 ft long, were placed along the face of the dam. Inasmuch as this entire area is submerged, great care was taken to braze all joints thoroughly, and to break the network into several parts, the terminals of which were brought in through the face of the dam and connected together inside by 2 500,000-cir-mil cables running through the inspection tunnel. The loss of one or more of these incoming feeders from the network should not reduce seriously the protective value of the ground.

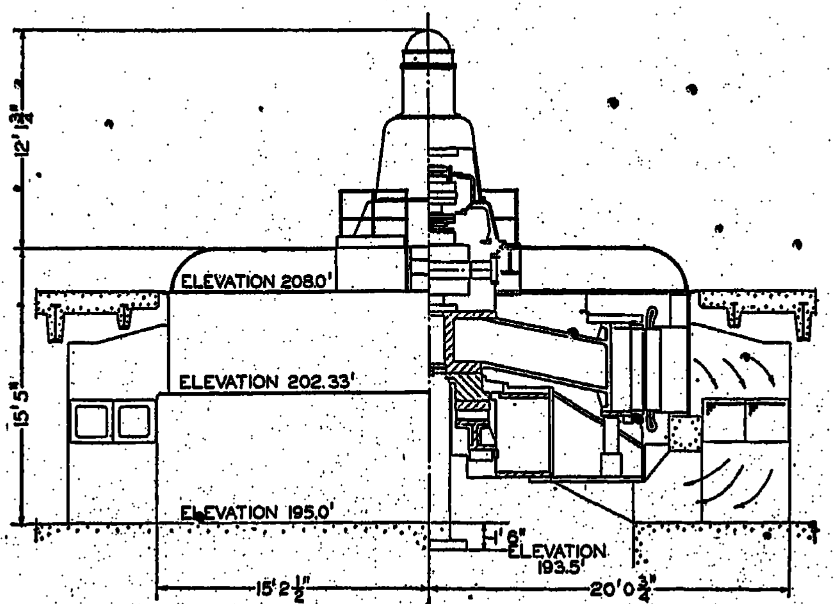

Fig. 7. Cross-section through a main 60-cycle generator

To obtain a direct path for lightning arrester grounds, several 1,000,000-cir-mil cables were carried from the lightning arrester location on the roof, out into the forebay, and terminated in connections to heavy rail sections. These cables were connected to gate guides and other submerged metal passed on the way to the forebay. It is expected that the amount of contact surface offered will give a fairly low resistance.

At the shore end of the power house directly adjacent to the rock fill on the railroad is a section of quiet water. It is expected that considerable silting will take place at this point; therefore, a network of cables, with a backbone of 500,000-cir-mil feeders, is laid there.

Two 500,000-cir-mil cables join the ground mats on the island with those in the forebay and those in the shore end of the forebay. In addition, heavy 5 x $^1/_4$-in. copper buses in parallel with these cables connect all grounds in the power house area. From these heavy buses are run auxiliary grounds to all sections of the station. Transformer banks are connected directly by short loops to the cables from the lightning arresters to the forebay. Transmission line ground wires are tied to the power house grounding system at several points in the vicinity of the power house.

## COMMUNICATION

A Bell telephone system with a central exchange located in the control room is used for telephone communication throughout the power house. This is supplemented by an autocall system with stations throughout the power house, dam, and substations, and by an operating-order signal system between switchboard and turbine gage boards on the operating floor. To advise the operating staff of unusual operating conditions, a system of telephone annunciator drops is used.

## RELAYS

Both the main and house generators are equipped with differential relays which shut down the unit completely. They are equipped also with overspeed and over-voltage relays with contacts in series. These act to open the main and field breakers and to bring the unit to rated speed with no load.

Provision is made for differential protection on the main buses; however, this protection is not yet installed.

Main transformer banks are equipped with differential relays, which protect a zone between the high-voltage bushing current transformers and the low-voltage bus. The 230-kv transformers are equipped in addition with a high voltage winding differential scheme.

As each of the main transformer banks is connected directly to a line, line and transformer protection is somewhat correlated. High speed impedance relays are used as protection against phase-to-phase faults. These are backed up by straight overload relays. Inasmuch as there are at present no high voltage buses on the system, ground protection is secured by the use of relays connected in the neutrals of the power transformers.

### MAIN TURBINES

An outstanding feature of the plant is the Kaplan turbines, the blades of which are adjusted automatically as the load changes, to maintain high efficiency over a wide range of load; also, the relation between blade angle and gate opening can be varied manually to compensate for changes in head.

[Editor's Note: For details of the design and setting of these turbines see "Kaplan Turbines for Safe Harbor Hydroelectric Plant," by Davis and Spaulding, ELECTRICAL ENGINEERING, October 1932, p. 728–33.]

Selection of this type of turbine followed an extensive investigation covering turbine units equipped with the 4 principal types of runners, namely, the Francis type, the propeller high speed type with fixed blades, the propeller high speed type with manually adjustable blades, and the Kaplan high speed type.

To eliminate the objection of poor economy under varying loads, an investigation was made of the use of one Kaplan unit with governor adjusted runner blades, in combination with 5 propeller fixed blade runner units. The horsepower-efficiency characteristic of the Kaplan runner is quite flat and, consequently, high efficiencies are maintained as the load on the unit is reduced. With such a combination of units, and with the propeller fixed-blade runner units all operating at best efficiency and the Kaplan unit taking the load swings, reasonably good economy in the use of water may be secured.

Kaplan runners with their adjustable feature may be operated with the blades wider open than the fixed blade position on the propeller runner. Consequently, for a given wheel diameter, the Kaplan runner will have a higher maximum power, or, with the same power, a smaller runner diameter with a corresponding reduction in the spacing between units may be secured. The higher capacities are, of course, contingent upon the runners being set sufficiently low for these capacities to fall within the power limits set by cavitation.

For small turbines the difference in first cost between Kaplan turbines and turbines with fixed blade runners is appreciable; as the turbine size increases, however, the percentage difference becomes less, and for units of the size selected for Safe Harbor, becomes small and is practically negligible compared with the total cost of the development. As the units in this station are required to furnish energy over 2 separate systems, it was decided that at least 2 Kaplan units should be installed for each system group, so that one will be available at all times for economical regulation of the load should the other unit be out of service. In addition to the foregoing, certain other advantages accrued from the use of *all* Kaplan turbines with automatically adjustable blades as finally selected for this plant. These are the highest powered Kaplan turbines in the world; the runners are 220 in. in diameter, and will discharge about 9,000 cfs at full gate and normal head.

Two means of unwatering the wheel casing have been provided. In one scheme the tailwater can be lowered automatically by admitting compressed air to the wheel casings. As the gates on these units approach the no-load position, an air valve will open and admit compressed air to the wheel casing. If the gates are closed, as when running reserve, or as a synchronous condenser, air pressure will be maintained automatically in the wheel casing and will depress the water level below the runner. The alternative method of unwatering the turbines for inspection or maintenance is to put stoplogs in the discharge end of the draft tube and pump out the water with portable 10,000-gpm unwatering pumps.

Speed rings are of cast iron in 4 sections, containing a total of 20 stationary vanes cast integrally with the upper and lower rings; the over-all diameter is approximately 28 ft 10 in. The speed ring and stationary speed ring vanes are cored hollow, and provision has been made for introducing steam inside the vanes as a protection against the accumulation of frazil ice. Provision also has been made for the discharge of steam into the scroll cases, after these passages have been unwatered, to aid in dislodging any frazil ice which may have formed, and to sterilize the wheel pits.

Turbine guide bearings are of the babbitt lined, oil lubricated type. One belt driven pump is used to circulate the oil in normal operation. A motor-driven pump also is installed to start automatically through the action of a flowmeter should the flow of lubricating oil in the supply line be reduced to the minimum quantity required for proper lubrication.

Turbine operating mechanism consists of 20 movable cast steel gates actuated through 2 oil pressure cylinders connected to the gates through an operating ring and suitable links and levers. This mechanism is protected from injury by the use of shearing pins inserted through the upper and lower sections of the gate lever, one section of which is keyed to the gate stem.

### GOVERNORS AND PUMPING SYSTEMS

Governor equipment is required to perform the double function of regulating the speed and controlling the pitch of the runner blades. Consideration was given to the following features: degree of protection against outage of the units due to failure of any part of the governor system; sensitive regulation of speed; convenience in operation; space required. After carefully considering 3 types of governing systems, the twin system was adopted; this system includes for each pair of units: 2 governors, 2 motor-driven pumps, 2 pairs of pressure tanks, and one common sump tank with 2 compartments.

Governors are of the oil pressure actuator type with motor-driven flyballs; they are of light construction, a desirable characteristic for sensitive operation and quick response to changes in speed.

Pumps are of the herringbone gear type, motor driven. This equipment is interconnected so that one pump may be used for the operation of either one or both of the main units and the second pump held in reserve as a spare unit. Each pump is equipped with a pressure starting switch to provide for the automatic starting of the pump held in reserve should the pressure in the supply tanks fall below the minimum pressure limit setting for the first pump. Unloader valves are installed to permit continuous operation of these pumps, if desired, in which case the oil will be by-passed automatically to the sump tanks when no additional fluid is required in the pressure tanks. Should it be found desirable to take either pair of pressure tanks out of service at any time, the pipe connections are such that both main units may remain in service, with one on governor and the other on hand control.

With this arrangement of equipment, a high degree of protection against outage is obtained, as the 2 main units served by each system may continue to operate with any one piece of governor system equipment temporarily out of service.

Each governor is equipped with a safety shutdown torque motor and solenoid switch, to provide for automatic closure of the turbine gates, to either the speed no-load or completely closed position through the operation of any one of several protective relays. Characteristics of the torque motor are such that it will not permit the opening of the turbine gates beyond speed no-load position until the voltage has reached from 50 to 60 per cent of normal (at which voltage the flyballs will assume control) except by hand through the release of a mechanical lifter. It is designed, also, to prevent the gates from opening when starting up should one phase of the three-phase governor flyball motor circuit be open. After the motor has been placed in service, the gates will be closed automatically when voltage drops to approximately 40 per cent of normal, but will remain open with one of the 3 phases of the governor supply open, should the voltage remain approximately normal. Governor flyball motors are driven from the pilot exciters on the main unit shafts through slip rings, and operate at 163 volts, 7.27 cycles.

Movement of the turbine blades is accomplished through a piston in the shaft cylinder, which is connected with the operating mechanism in the runner hub through a vertical rod within the turbine shaft. The piston is operated under oil pressure admitted to and discharged from the cylinder through 2 concentric pipes within the generator section of shaft. For every position of the turbine gates, the runner blades are moved to a corresponding position to develop the best turbine efficiencies through a wide range of load. The flow of oil to and from the shaft cylinder is controlled by a valve connected through a cam to the turbine gate operating mechanism. The relation of the turbine gate openings to the position of the runner blades is allowed to remain fixed within approximately a 4-ft variation in head. Beyond this range other cams, which may be quickly and conveniently shifted into position, are employed to insure reasonably high efficiencies under a wide variation of head.

# A Résumé of Progress in Insulation Research

**Steadily pioneering uncharted paths, the continuing efforts of those directing and participating in the uncovering and correlation of new knowledge in the field of dielectrics are laying foundations for the further development of electrical apparatus. A brief insight into some of these activities is given here.**

By
JOHN B. WHITEHEAD
FELLOW A.I.E.E.
The Johns Hopkins Univ.,
Baltimore, Md.

As IN PRECEDING years, principal attention in this brief presentation is devoted to a survey of the literature of dielectrics and insulation as it has come to attention during the past year. Comments are based upon the reading of some 30 or 40 scientific papers, a list of which may be found at the close of this article. Since the topics vary over the whole field, from basic theory to large scale applications, the difficulty of a systematic division and the impossibility of anything more than a passing comment on the most important aspects of all this work may be appreciated.

## GASES

An important series of optical studies of the beginning of spark discharge is reported by Lawrence and Dunnington. Using a Kerr cell between crossed Nicol prisms, photographs of sparks $4 \times 10^{-8}$ sec after the application of voltage, as well as measurements of the broadening of spectrum lines and of the instantaneous current and temperature, have shown current densities of $1.7 \times 10^6$ amp per sq cm in the spark; have revealed inter-ionic fields of $10^6$ volts per cm, and the ionization of $1/3$ of the total number of molecules; and have shown temperatures of the order of 10,000 deg K in the spark. These results support Slepian's theory of thermal ionization.

By experiments in a uniform field Inge and Walther have studied the flashover of solid insulators. It is stated that flashover is always a breakdown of the air. This breakdown is influenced, however, by moisture or other condition of the solid surface, through auxiliary ionization and unequal potential gradient; clean, dry surfaces in a uniform field

flash over at the same voltage as the air when the dielectric is removed.

Interesting results on the decomposition of gases under electrical discharge are reported by Linder and Davis. Under glow discharge it is found that in a series of similar hydrocarbon compounds of increasing molecular weight the rate of gas evolution per unit current increases with the molecular weight, whereas in a series of the same molecular weight it increases with decreasing centralization. In another paper the ionization and dissociation of benzene and carbon-bisulphid under electron impact have been studied by spectrographic methods. Interesting data are recorded as to the nature and numbers of the resulting ions and conclusions are reached as to the stability of the bonds in the original molecule. These experiments have as their ultimate object the determination of information as to the chemical reaction in electrical discharges, with particular reference to the causes of the generation of gas in high voltage impregnated paper cables.

## LIQUIDS

The outstanding contribution in the field of liquid dielectrics is a series of 6 or more papers by A. Nikuradse, of the Technische Hochschule of Munich, concerning ionization, conductivity, and breakdown in insulating oils. These papers for the most part center about careful observations of the current-voltage curves under controlled conditions, and of similarly controlled breakdown tests over a wide range of frequency as related to the same oils. Good evidence is produced that the continuous current-voltage curve is of the same shape as that pertaining to gases. The saturation region is shown clearly, and in particular the ascending portion of the curve at higher voltages has been examined over a wide range of conditions. Temperature variations in the curves, and the increase of current with increased distance between electrodes, permit the computation of ionization coefficients and strengthen the theory of secondary ionization as the underlying cause of breakdown. In these experiments, purification was accomplished by drying, filtration, and successive distillation in an unusually elaborate experimental set-up. A definite residual conductivity always was found. The saturation phenomenon remains, and there are evidences of space charge of other polarity effects as related to the shape and materials of the electrodes. In the work on breakdown, one of the most striking features is the great increase in dielectric strength that may be reached by purification, this increase being of the order of from 100 to 1,000 times the values commonly attributed to good commercial insulating oils. The purer the oil, the less the influence of both pressure and temperature. For decreasing time of voltage application, the breakdown voltage for both pure and impure liquids approaches the same value, $1.3 \times 10^6$ volts per cm, at an impulse voltage of duration of the order $10^{-10}$. The influence that air in solution in an insulating oil has upon the behavior when electric stress is applied has been studied by Koppleman. Data on the relation to breakdown are submitted.

It should be noted that in this work Nikuradse has not studied the question of behavior under alternating stress except in the matter of breakdown. The continuous current-voltage relations are those pertaining to the long time or steady state. Current and loss relations under alternating stress are associated with an initial or short time value of conductivity that may be quite different to that observed in the steady state under continuous potential. The steady alternating behavior as related to this type of short time conductivity has been continued at Johns Hopkins using several highly refined and carefully protected oils of the commercial insulating group. It has been shown that in the low range of frequencies the losses and power factors of these oils are completely accounted for by an initial value of d-c conductivity having a duration of the order of one second. The conductivity is clearly ionic and there appears to be no reason to invoke any type of loss other than that due to the friction of ionic translation within the liquid.

Several studies of refined insulating liquids in small cells having as their object the correlation of molecular and electrical performance are known to be under way, but no important results have been reported during the year.

Action of cathode rays on hydrocarbon liquids has been studied by Schoepfle and Fellows, and in other experiments in the laboratories of the Detroit Edison Company. The gaseous products of several hydrocarbons under fixed conditions of bombardment are reported. Certain correlations have been found between the amount of gas and the molecular structure. Saturated hydrocarbons give large amounts of gas, whereas unsaturated hydrocarbons give small amounts of gas. Aromatic hydrocarbons give practically no gas. These experiments are directed particularly toward the conditions underlying the liberation of gas in high voltage cables, and seek information as to the relative stabilities of various oils under electric influence.

## SOLIDS

Most of the contributions in connection with solid dielectrics have a theoretical trend. P. Böning has continued his contributions expounding his theory of adsorption by colloid particles of the ions of one sign, and the passage to the electrodes of the ions of opposite sign, thus creating space charges and high values of potential gradient. The theory is developed particularly for liquid insulators, but is extended to include impregnated materials and others in which the liquid phase obtains to some extent. The most recent contribution deals specifically with the application of the theory of the behavior of impregnated paper, with particular consideration of space charge and potential gradient.

In a paper entitled, "What Is an Insulator?" Meissner proposes that the characteristic properties of insulators lie in the elementary crystal cell. The influence of the type of lattice, the nature of the bonds, and the intensities of the fields are discussed and correlated with experiments on piezo and pyro phenomena in crystalline and amorphous quartz.

The behavior of complex dielectrics also is discussed and the statement made that these, in general, if fused and allowed to solidify while under electric stress, also will show the pyro and piezo effects.

Debye's theory of molecular orientation as an explanation of dielectric loss in solid and semi-solid materials continues to be a topic of interest. An interesting series of experiments carried on by H. H. Race on electric and other physical properties of insulating oils, notably of oxidation and the spread of oil on water, support only partially the explanation of dielectric loss as a Debye effect. Oxidation increases the loss, but not the frequency at which maximum occurs. However, the spread on water is increased and this is an evidence of a polar property. A substantial loss factor remains after the computation of the Debye loss, indicating some other loss.

Measurements of dielectric constant and power factor of rosin oil and ethyl abietate in the range of frequency from 10 cycles to 100 kc and over the temperature range from $-65$ to $+20$ deg C, and other measurements made on certain glycols in the frequency range from 1 to 100 kc and with temperatures ranging down to $-90$ deg C have been made by White and Morgan. The particular interest of these substances is that their viscosity increases greatly within the temperature ranges mentioned, so that the anomalous dispersion or change of dielectric constant and also the maxima of power factor may be traversed into the measurements. Good agreement as between experiment and the Debye theory was found for a pure glycol, but some divergence in the case of a solution. Similar qualitative agreement was found by the same authors in rosin oil. At Johns Hopkins, experiments have shown that in the low frequency (60 cycles) range the observed variation in power factor and capacitance or dielectric constant with temperature may be accounted for in terms of a polarization arising first in the separation of space charges and later, as the solid phase is approached, in terms of the Maxwell dielectric absorption. So far as the losses in well known insulating liquids and in the more complex combinations for commercial insulation at 60 cycles are concerned, there seems to be general agreement that types of polarization other than that due to molecular orientation are well recognized, and under the Maxwell-von Schweidler theory of dielectric absorption are sufficient to account for the observed values of power factor and dielectric constant and their variations. If polar molecules are present, their contributions to these variations probably are small. At present, the most promising means of distinguishing between these two effects is to find a material in which there are two regions where the dielectric constant changes with frequency. In fact, Gemant has called attention to the fact that three such regions are to be expected, the third region being that of normal or optical dispersion due to the inertia of the charges within the body of the atom. Gemant places the range of frequency for the Maxwell-Wagner power factor maximum and corresponding anomalous dispersion at from 1 to $10^5$ cycles, whereas the Debye region is from $10^6$ to $10^{13}$, and the inner atomic region is around $10^{14}$ cycles.

The mechanism of the breakdown in solids has been discussed in an extensive paper by Joffé in which he includes brief accounts of many experiments which heretofore have been published only in Russian. They are now and will be in the future available in the Physikalische Zeitschrift der Sowjetunion, which is printed in German. Experiments are reported indicating that the breakdown voltages of natural, carefully tempered, and strongly deformed rock salt, colored by exposure to Röntgen rays, were found to be identical for impulse and continuous voltages, a result which the author feels proves that internal crystal cleavages have no bearing upon the mechanism of breakdown, just as the same author has shown that they have no influence upon the electric conductivity. Ionization by collision is studied in thin layers, in which case the ionization leads to a stationary current easily measured, instead of to breakdown. This peculiarity of thin layers is related intimately to their higher dielectric strength. As observed in mica and glass in layers 0.005 mm thick, dielectric strengths of $50 \times 10^6$ volts per cm were reached. The same phenomenon also was observed in pure gas-free liquids. Whereas, in thick layers, breakdown due to impulse or collision ionization is independent of the temperature, in thin layers the breakdown voltage is lowered with rising temperature until it reaches the thick layer value at the temperature of thermal breakdown. These facts lead to the conclusion that impulse ionization is caused by mobile ions and not in any way by electrons due to radio active influence. Nevertheless, it seems to indicate that an avalanche of ions leads to breakdown when the necessary initial conditions for thermal breakdown are present. The increased conduction due to ionization by collision, if not carried to breakdown, vanishes very quickly. In thin mica the recombination time is less than 0.003 sec.

## COMMERCIAL INSULATION

From a great deal of experimental and development work in this field, space limitations permit the mention of only 1 or 2 examples that are of particular significance. Gemant has proposed a new theoretical analysis of the rising power factor-voltage curve for impregnated paper containing gas layers. It is based upon the assumption that the breakdown of a thin air layer is limited to about 350 volts and that after breakdown the difference of potential over the air layer becomes zero and the ionization current stops. Further discharge can take place only by further increase of the applied over-all voltage or by its reversal. Thus, during the alternating cycle of maximum value just sufficient to cause breakdown, there will be 4 such breakdowns in one cycle. If the applied voltage is double or three times that necessary to cause the first breakdown, the number of discharges will be 8 and 12, respectively, etc. The author attempts a mathematical extension of this idea to the general case as based on thermal relations. The curves as derived agree generally with those observed, and the author claims that the usual power factor-voltage curve as measured may, by use of his formula, be used as an indication of the density of air layers within the insulation.

Whitehead and Baños, working with 10 different insulating oils, have shown that the dielectric loss in impregnated paper consists of 2 components, one due to conduction and the other to dielectric absorption; and further that a general relation exists between each of these components of loss, and the common physical properties of the impregnating oil. Baker and James have shown in qualitative manner the existence of soft X-rays and unequal potential distribution in impregnated paper. Wood and Brobst have reported the treatment of textile insulation with cellulose acetate, with resulting lowering of leakage conductance, the action apparently being due to the laying down of the fibers.

## HIGH VOLTAGE CABLES

A great deal of experiment and observation on cables, both in service and in laboratories, is being conducted by prominent utility companies. These studies have to do largely with the influence of temperature cycles on loss and power factor as related to stability, and in several instances are paralleled by accelerated life tests. Particular attention is being given to the performance of oil filled cables, and to the question of the possible reduction in thicknesses of insulation. Other questions receiving attention are a suitable aging test, the deterioration of impregnating oils under electric discharge, the thermal resistivity of insulation, and the imperfections of lead sheath due to corrosion and other causes. Reports of these various studies are commonly circulated within the N.E.L.A., the Association of Edison Illuminating Companies, and the bulletins of the Electrical Testing Laboratories. These reports are familiar to many persons, and as they are not published no attempt has been made to record them in detail in this report. An interesting survey of modern design, construction, and operation of high voltage cables will be found in a group of papers presented to the International Electrical Congress in Paris this last summer.

## MONOGRAPHS

While the issuance of another monograph has been impossible during the year just closing, substantial progress has been made toward the completion of further volumes in the series of monographs on dielectrics and insulation to be published under the auspices of the National Research Council's committee of electrical insulation. The first in the series, as may be remembered, was "The Nature of a Gas," prepared by Prof. L. B. Loeb of the University of California, Berkeley, Calif. The manuscript of the second in the series—"Liquid Dielectrics," by Dr. Andreas Gemant—is in hand and now is in process of preparation for publication. Progress is being made on 5 additional monographs:

Electric Discharge in Gases, by K. T. Compton and Irving Langmuir

Conduction in Gases, by J. Slepian and R. G. Mason

Solid Dielectrics, by C. F. Hill

Electrical Properties of Glass, by J. T. Littleton

Chemical Effects in Electric Discharge, by Geo. Glockler and S. C. Lind

# Out-of-Step Conditions on a Synchronous System

By
ALEX A. KRONEBERG
ASSOCIATE A.I.E.E.
Southern Calif. Edison Co., Ltd., Los Angeles, Calif.

**During out-of-step conditions on a synchronous system, a state of equilibrium may be reached under which the system will neither accelerate nor retard until conditions are changed by switching operations, or by removal of synchronous condensers. Proof of this theory is given for a condition where the synchronous condensers were operating at 35 cycles (70 per cent of normal), the generators at normal speed of 50 cycles, and induction motors, with a load varying as the square of speed, operating at 65 per cent of synchronous speed.**

On SEVERAL OCCASIONS it was observed that when out-of-step conditions exist on the system of the Southern California Edison Company, Ltd., the synchronous condensers slow down to about 35 cycles per second and run at that speed until switched off the line or until operating conditions are altered in some other way. To determine the proper procedure for quick restoration of synchronism an actual out-of-step condition was exhaustively analyzed; the results of that analysis are given in this article. For some time several methods have been available for determining the power limits of a transmission system under steady state and transient conditions, but little is known of the behavior of systems when definitely out of step. The subject of system stability as presented up to this time has been treated as a problem of *maintaining* stability, whereas this article gives prime attention to the problem of *regaining* stability.

## SYNCHRONOUS POWER

The first step in evolving a method of solution was to consider the power equation of a synchronous machine:

$$P_m \sin \delta + P_r = P \qquad (1)$$

In this equation, which is accurate enough for the purpose involved, the terms representing electrical power are grouped on the left side of the equation and are equal to $P$, which is mechanical power. The term $P_m$ is the maximum synchronizing power that can be exchanged between the generator and the equivalent synchronous machine, which represents all the remaining synchronous machinery of the system. $P_r$ includes the internal losses and power supplied to resistance loads. Synchronism will be lost when the angle $\delta$ exceeds 90° and $P_m + P_r$ becomes equal to or less than $P$. From then on the synchronous power $P_m$ alternates from positive to negative. The net power applied to the rotating parts of the generating unit is equal to the algebraic difference of the 2 sides of eq 1. This is shown in Fig. 1.

In most cases $P_m$ is larger than $P_r$; hence when $\delta$ reaches the magnitude of 270° the left side of eq 1 becomes an input of power from the slower system to the faster generator. It can be shown that if $P$ could be made equal to $P_r$ during out-of-step conditions, the generator would continue to run at some average constant speed, but out of synchronism. Were $P$ reduced to a value lower than $P_r$ the generator would retard and eventually fall in step with the system. This reduction of $P$ is effected by the governor of the prime mover, but is not fast enough to prevent considerable disturbance of the system.

## INERTIA

However, eq 1 is true only under normal operating conditions and approximate for small deviations from synchronous speed. An important term has been omitted in the foregoing discussion that must be introduced into the equation when transients and out-of-step conditions are being investigated. The net power applied to the rotating parts of the generating unit has been mentioned already. Power applied to a rotating body having a certain angular

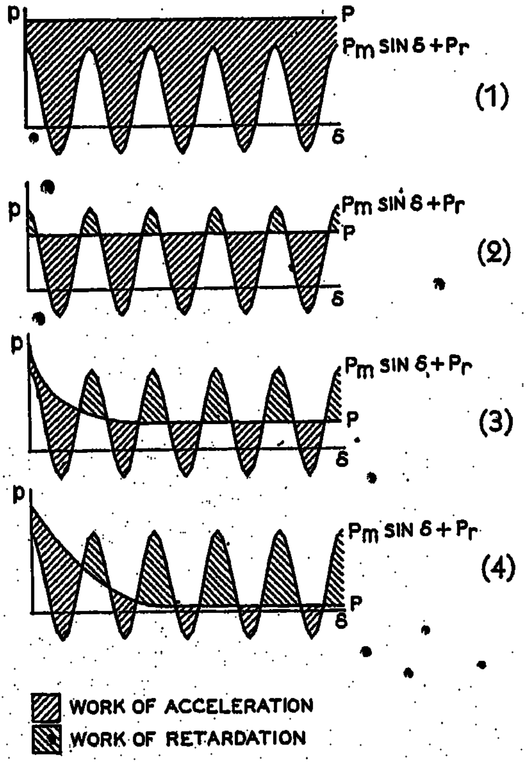

**Fig. 1. Input and output of a synchronous generator when running out of synchronism expressed as functions of angle between internal voltages of the generator and the combined synchronous machinery**

1. P larger than $P_m + P_r$
2. P smaller than $P_m + P_r$ but larger than $P_r$
3. P is made equal to $P_r$
4. P is made smaller than $P_r$

---

Prepared especially for ELECTRICAL ENGINEERING. Written discussion is invited and will be published in so far as space and other controlling factors permit. *Not published in pamphlet form.*

momentum (sometimes called moment of momentum) will cause acceleration or retardation, depending upon the direction of the power applied. Either the generator or the system can be taken as a reference and a relative inertia term assigned to the other. Remembering further that the relative acceleration of the 2 is the second derivative of their angular displacement, eq 1 can be expressed as follows:

$$P_i \frac{d^2\delta}{dt^2} + P_m \sin \delta + P_r = P \qquad (2)$$

This equation represents synchronous machines with very little damping or induction motor characteristics; for transient stability calculations at or near synchronous speed, it is being used in this form or its equivalent in torque terms.

### INDUCTION MACHINE CHARACTERISTICS

Synchronous machines have some damping as an inherent characteristic in addition to the damping introduced into their design to stabilize them in operation and to improve their starting characteristics. Damping is equivalent to the induction machine characteristics that exist in the field structure of the synchronous machine. A certain amount of damping is introduced by the field circuit itself when completed through the armature of the exciter, by the damper windings when present, and by the iron of the field structure. As in induction machines, the power due to damping is a function of terminal voltage and difference of speeds or the first derivative of angular displacement. By introducing the damping term in eq 2 the following equation is obtained:

$$P_i \frac{d^2\delta}{dt^2} + P_d \frac{d\delta}{dt} + P_m \sin \delta + P_r = P \qquad (3)$$

This is the general equation of a synchronous machine and its development is described by W. V. Lyon and H. E. Edgerton, in their paper "Transient Torque-Angle Characteristics of Synchronous Machines" (A.I.E.E. TRANS., v. 49, April 1930, p. 686–99.)

### OUT-OF-STEP OPERATION

Unfortunately eq 3, which is a differential equation, has not been solved; that is, presented in the form

$$\delta = f(t) \qquad (4)$$

Were such a solution available, all stability and out-of-step problems could be solved easily in terms of time. As it stands, problems of this kind must be dealt with by making various assumptions and approximations, or by making long and tedious step-by-step calculations.

The assumption which led to the method of calculation of out-of-step operation now will be discussed. As was observed in actual operation, the difference in speeds of generators and condensers was constant for a period of minutes. This being the case, the angle $\delta$ was assumed to be a straight line function of time $(Kt + \delta_o)$:

$$P_d K + P_m \sin (Kt + \delta_o) + P_r = P \qquad (5)$$

The average can be found by integrating with respect to $dt$ between limits of $O$ and $\frac{2\pi}{K}$ and dividing by $\frac{2\pi}{K}$. The final equation will be

$$P_d K + P_r = P \qquad (6)$$

Equation 6 can be interpreted to mean that when a synchronous generator is out of step, and running at constant speed, the synchronizing power is pulsating and the average value is zero. The input then must be equal to the total of losses, resistance loads, and output as an induction generator. When a condenser or synchronous motor is out of step and running at a constant speed the mechanical output, losses, and electrical output due to internal voltage must be equal to the input as to an induction motor.

The assumption of $\delta$ being a straight line function of time is not correct in a strict mathematical solution, but a substitution of typical numerical values and a step-by-step solution would demonstrate the permissibility of that assumption, because the result is quite accurate for practical purposes.

### METHOD OF COMPUTATION

When machines of different characteristics are connected to the same system and are out of step, 2 or more frequencies are imposed on the system. The method of analyzing a condition of this kind is discussed in the following paragraphs.

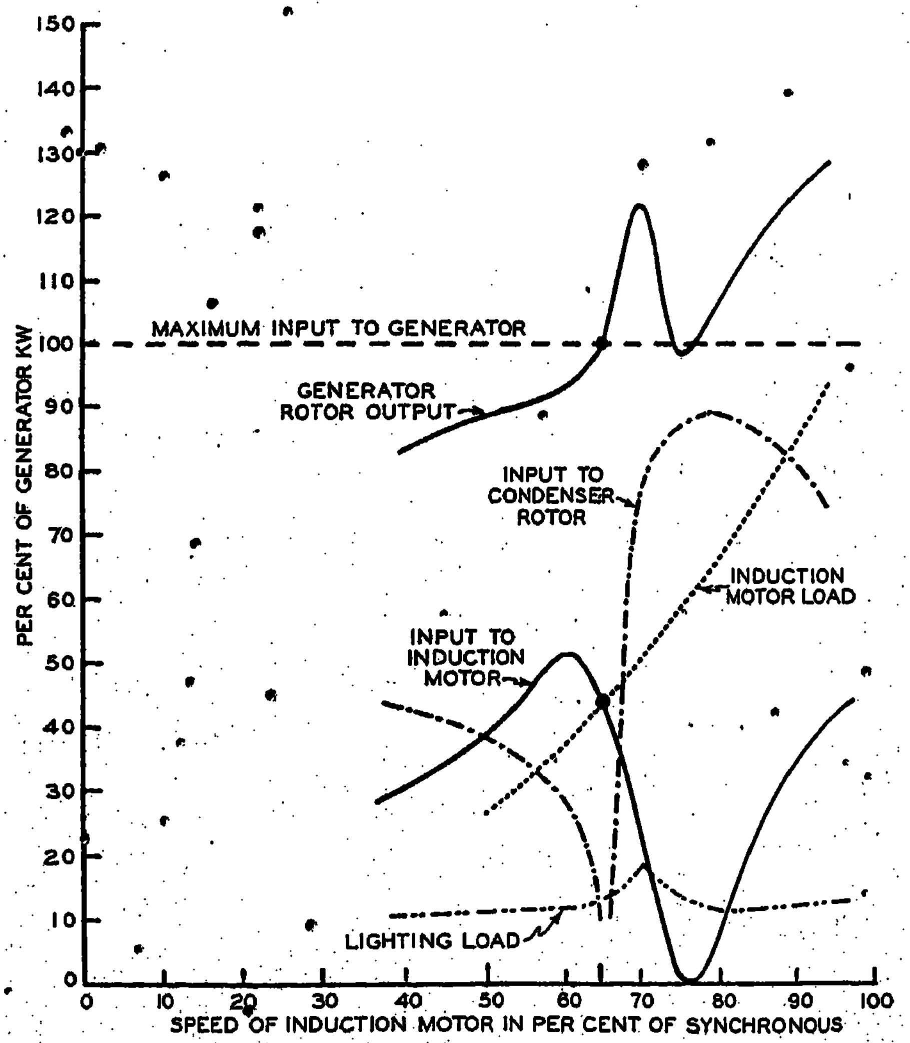

**Fig. 2. Power input and output of machines expressed as functions of speed of induction motor**

System consists of 200,000 kw of steam generating capacity, 240,000 kva of synchronous condensers, 190,000 kw of induction motor load, and 50,000 kw of resistance load. The generators are operating at normal speed while the condensers are operating at 70 percent of synchronous speed

Consider a simple system composed of a generator, a short transmission line, a synchronous condenser with damper windings, an induction motor with a load varying as the square of its speed, and some resistance or lighting load. The generator is running at 50 cycles, the condenser at 35 cycles. The problem is to determine the speed of the induction motor and the power flow in the circuits. To do this, the 2 synchronous machines are considered as consisting of an ideal synchronous machine solidly coupled mechanically to an induction machine having characteristics similar to those of the original machine. Under normal synchronous operation both component machines would be connected to the same circuit and the induction part would be driven at synchronous speed with respect to the system thus having zero power output, but during out-of-step conditions 2 systems must be considered. One of these is a 50-cycle system composed of the synchronous generator supplying power to the induction motor characteristics of the synchronous condenser which is operating at a 30 per cent slip, in addition to the power required by the induction motor and resistance load; the other, a 35-cycle system composed of an induction generator operating at 43 per cent positive slip and supplying power to the induction motor and resistance load by virtue of the fact that the induction characteristics of the synchronous generator receive excitation from the synchronous condensers at 35 cycles. Power inputs and outputs of the units in both systems can be computed and the results superposed. The results then are plotted as functions of induction motor speed.

In Fig. 2 are shown results of computations of a condition experienced on a portion of the system of the Southern California Edison Company, Ltd., after an out-of-step condition had occurred and the system had been separated into 3 independent sections. The section under consideration included 200,000 kw of steam-electric generating capacity, 240,000 kva of synchronous condensers, a normal 190,000 kw of induction motor load, and 50,000 kw of resistance load. The speed of the generators at the time represented in Fig. 2 was normal, but that of the condensers was observed to be but 70 per cent of normal, or 35 cycles per second. As may be seen from Fig. 2 the induction motor was running at about 65 per cent of synchronous speed, as the dual frequency input at that speed balanced the load. The induction motor load under these conditions amounted to 44 per cent of generator input or 88,000 kw, the lighting load amounted to 12 per cent of generator input or 24,000 kw, and the bus voltage was 69 per cent of normal. The remainder of the generator input was absorbed in generator, transformer, line, and condenser losses. The generators were carrying full load and could not develop any additional power to accelerate either the condensers or the induction motors. The induction motors did not slow down because at lower speeds their input would have exceeded their load.

With conditions of this kind established on the system it is necessary to switch the condensers off until after the induction motors are accelerated to normal speed with respect to the generators. Then the condensers can be resynchronized. If the system be allowed to operate for any length of time under conditions like those just described the condenser and generator damper windings and field structures will overheat rapidly and eventually burn out.

## DETAILS OF CALCULATION

Some of the details of calculating out-of-step conditions are indicated in the following brief outline.

Nomenclature:
$E_1$ —internal voltage of generator
$E_2$ —internal voltage of condenser
$\dot{Z}_1$ —impedance of generator to bus
$\dot{Z}_2$ —impedance of condenser to bus
$V$ —bus voltage
$R$ —resistance shunt
$\dot{Z}_1''$—impedance of equivalent induction generator driven at $f_1$ cycles on an $f_2$-cycle bus
$\dot{Z}_3'$—impedance of induction motor at speed $S_3$ on an $f_1$-cycle bus
$\dot{Z}_3''$—impedance of induction motor at speed $S_3$ on an $f_2$-cycle bus
$\dot{Z}_2'$—impedance of synchronous condenser at speed $f_2$ cycles on an $f_1$-cycle bus
$\dot{Y}'$ —total admittance of circuits at $f_1$ cycles from air gap of generator
$\dot{Y}''$ —total admittance of circuits at $f_2$ cycles from air gap of synchronous condenser

There will be 2 electromotive forces in the circuit. If $f$ is the normal frequency,

$$E_1' = \frac{f_1}{f} E_1 \quad \text{and} \quad E_2'' = \frac{f_2}{f} E_2$$

The generator output will be

$$P_1 + jQ_1 = \frac{f_1}{f} \dot{E}_1 \dot{V}' \dot{Y}' - \frac{(V'')^2}{\dot{Z}_1''}$$

Condenser input (or output)

$$P_2 + jQ_2 = \frac{f_2}{f} \dot{E}_2 \dot{V}'' \dot{Y}'' - \frac{(V')^2}{Z'_2}$$

Induction motor input

$$P_3 + jQ_3 = \frac{(V')^2}{\dot{Z}_3'} + \frac{(V'')^2}{\dot{Z}_3''}$$

Resistance load

$$P_4 = \frac{(V')^2 + (V'')^2}{R}$$

Bus voltage

$$\frac{\dot{V}' = \frac{f_1}{f} E_1 - \left(\frac{f_1}{f}\right)^2 E_1 \dot{Y}' Z_1}{\dot{V}'' = \frac{f_2}{f} E_2 - \left(\frac{f_2}{f}\right)^2 E_2 \dot{Y}'' \dot{Z}_2}$$

The problem then consists in evaluating the impedances and admittances of the circuits, using all available data on machinery or making reasonable assumptions.

Generator input $= P_T$ (constant)
Motor load $= P_L S_3^2$ where $P_L =$ coefficient.

## PROOF OF SUPERPOSITION PRINCIPLE

If 2 frequencies having a ratio $r$

$f_1/f_2 = r$

are considered and expressions for instantaneous voltage and current in one phase to ground of the circuit are written

$$e_1 = E_1 \sin (r\omega t)$$
$$e_2 = E_2 \sin (\omega t)$$
$$i_1 = I_1 \sin (r\omega t + \theta_1)$$
$$i_2 = I_2 \sin (\omega t + \theta_2)$$

the powers (1 phase) are

$$P_1 = \frac{1}{2} E_1 I_1 \cos \theta_1$$

$$P_2 = \frac{1}{2} E_2 I_2 \cos \theta_2$$

and it is to be proved that

$$P_R = P_1 + P_2$$

The resultant voltage and current in the circuit are

$$e_R = E_1 \sin (r\omega t) + E_2 \sin (\omega t)$$
$$i_R = I_1 \sin (r\omega t + \theta_1) + I_2 \sin (\omega t + \theta_2)$$

and the instantaneous power is

$$P_R = e_R i_R = [E_1 \sin (r\omega t) + E_2 \sin (\omega t)] [I_1 \sin (r\omega t + \theta_1) + I_2 \sin (\omega t + \theta_2)]$$
$$P_R = E_1 I_1 \sin (r\omega t) \sin (r\omega t + \theta_1) + E_2 I_2 \sin (\omega t) \sin (\omega t + \theta_2) + E_1 I_2 \sin (r\omega t) \sin (\omega t + \theta_2) + E_2 I_1 \sin (\omega t) \sin (r\omega t + \theta_1)$$

Remembering that

$$\sin \alpha \sin \beta = \frac{1}{2} \cos (\alpha - \beta) - \frac{1}{2} \cos (\alpha + \beta)$$

we now have

$$2P_R = E_1 I_1 \cos \theta_1 + E_2 I_2 \cos \theta_2 - E_1 I_1 \cos (r\omega t + \theta_1) - E_2 I_2 \cos (\omega t + \theta_2) + E_1 I_2 \cos (\theta_2 + (1 - r)\omega t) - E_1 I_2 \cos (\theta_2 + (1 + r)\omega t) + E_2 I_1 \cos (\theta_1 + (1 - r)\omega t) - E_2 I_1 \cos (\theta_1 + (1 + r)\omega t)$$

The average value of power is

$$P = \frac{1}{T} \int_0^T ei dt$$

Let $O$ and $T$ satisfy the equation

$$\sin (\omega t) = \sin (r\omega t) = 0$$

and integrate the expression for $2P_R$. The process of integration is too complicated to show here, but the result is

$$2P_R = E_1 I_1 \cos \theta_1 + E_2 I_2 \cos \theta_2$$

and

$$P_R = \frac{1}{2} E_1 I_1 \cos \theta_1 + \frac{1}{2} E_2 I_2 \cos \theta_2$$

which is

$$P_R = P_1 + P_2$$

# A Theory of Neon Tube Operation

**Here is advanced a theory of luminous tube operation based upon an engineering study of the voltage and current waves associated with the discharge of electricity through neon gas.**

By
**CLAUDE M. SUMMERS** General Electric Company,
ASSOCIATE A.I.E.E. Fort Wayne, Ind.

SUCCESSFUL OPERATION of the popular cold cathode neon tube lighting system depends upon many factors, some of which are quite intricate and intangible. In this system a transformer which may have 97 per cent reactance and a secondary potential as high as 15 kv is used as a source of supply. The theory of operation of this system may be generally unknown, and it is the purpose of this article to promote a theory from an engineering standpoint based upon a study of the voltage and current waves associated with the discharge through the neon gas.

In its normal state neon gas is a relatively good insulator, but when ionized the gas becomes a conductor with a negative resistance characteristic. This means that the lower the voltage drop across a given length, the greater the current that flows through the gas. A volt-ampere curve of one particular type of neon tube is shown in Fig. 1. If the symbol $e_t$ represents the instantaneous value of voltage it can be expressed as some function of the current, thus

$$e_t = f(i) \qquad (1)$$

If a sinusoidal current wave passing through the gas be assumed, and if from the instantaneous values of current are found the corresponding values of voltage, the wave form of voltage necessary to produce this current can be determined. Such a wave form is shown in Fig. 2. It is not feasible, however, for a sine wave of current to flow through the neon gas because the ionization potential as shown in Fig. 1 is higher than the voltage necessary to maintain a current flow. The potential at the beginning of each half-cycle must rise to a value sufficiently high for ionization, then reduce to some value indicated by the curve in Fig. 1. It is evident that the current

---

Written especially for ELECTRICAL ENGINEERING. Based upon a paper originally read before the A.I.E.E. Fort Wayne, Ind., Section, this article supplements the information concerning luminous tubes as given in the articles published in ELECTRICAL ENGINEERING in August and November 1931. *Not published in pamphlet form.*

ust remain at zero for a short period of time during ach half-cycle, and as a result the wave form is more eaked than a sine wave. The actual wave form of urrent and voltage is shown by the oscillogram in ig. 3 which was obtained from a circuit employing a sistance instead of a reactance for limiting the urrent. This establishes 2 important facts: (1) at the current wave crosses the zero axis inside the

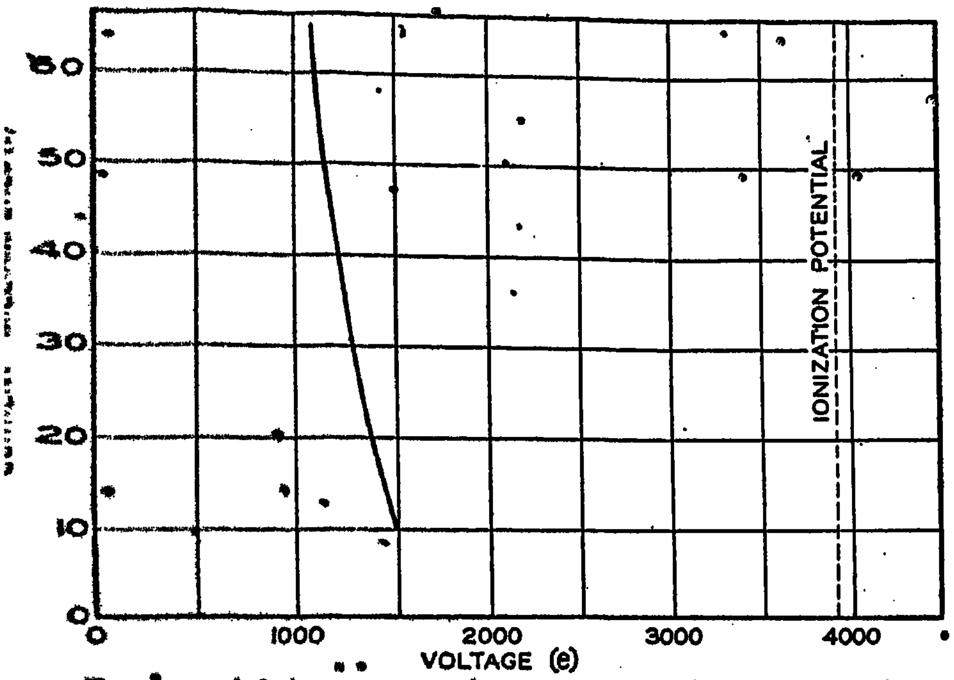

Fig. 1. Volt-ampere characteristics of one type of neon tubing including electrode and gas column

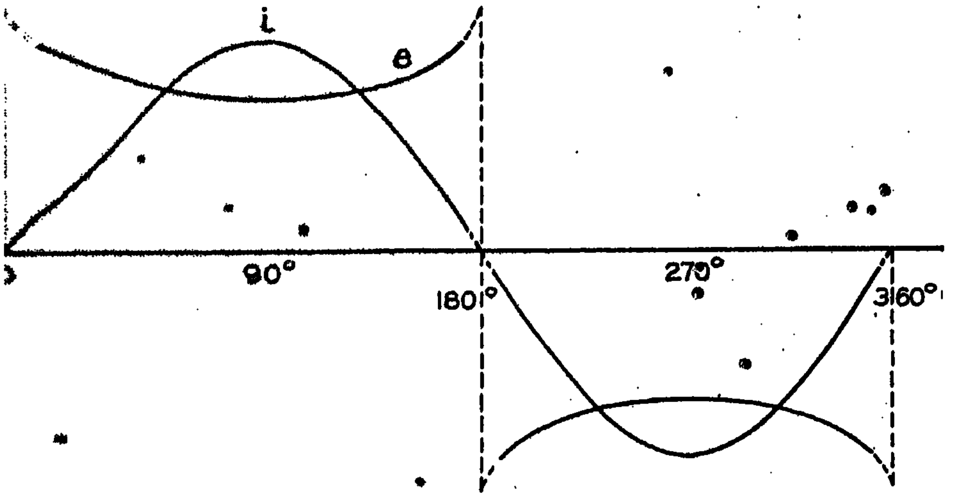

Fig. 2. Voltage wave (e) calculated from Fig. 1 assuming sinusoidal current (i)

nvelope of voltage wave, and in this respect the eon tubing acts as a resistance load requiring eaked current; (2) during each half-cycle the current actually is zero for a finite length of time.

Consider a high reactance transformer as repreented by the circuit in Fig. 4 which shows the rectance of a transformer concentrated in an inducance $L$ in the secondary circuit. Neglecting the esistance drop in both the transformer and the xternal inductance the voltage across the resistance oad may be represented by the equation

$${}_R = E_s - E_L \text{ vectorially} \qquad (2)$$

In eqs 1 and 2 the symbols $E$ indicate rms values. f instantaneous values are considered,

$$\begin{aligned} {}_R &= e_s - e_L \\ &= e_s - L\frac{di}{dt} \end{aligned} \qquad (3)$$

The vector and wave-form diagrams of Fig. 5 may represent, respectively, eqs 2 and 3, and from these diagrams it is clearly evident that the load voltage lags the induced or open circuit voltage by some angle $\phi$. If the load is of such a nature that a peaked current wave is established throughout the circuit, the differential of this current wave represented by $L\frac{di}{dt}$ will be a flat topped wave. When this flat voltage wave is subtracted from the open circuit voltage $e_s$ the load voltage wave $e_R$ also will be a flat topped wave as shown in Fig. 6. Thus it is possible for the current to assume such a form that the load voltage wave will be somewhat similar to that shown in Fig. 2 and therefore suitable for operating a neon tube load, at least for a portion of each half-cycle. When a neon tube load is substituted for a resistance load, the symbol $e_t$ should be substituted for $e_R$ in eqs 2 and 3. Thus there are 2 equations (1 and 4) which must be satisfied by the same value of current:

$$e_t = f(i) \qquad (1)$$

$$e_t = e_s - L\frac{di}{dt} \qquad (4)$$

When the neon tube load is placed across the secondary of the transformer the current follows a periodic variation. The instantaneous values of current not only must give some specific value of $e_t$ represented by eq 4, but the same instantaneous value of current must give the same value of $e_t$ when taken from the curve in Fig. 1 or from eq 1. The actual wave form of current, therefore, will be a compromise between a peaked wave and a sine wave.

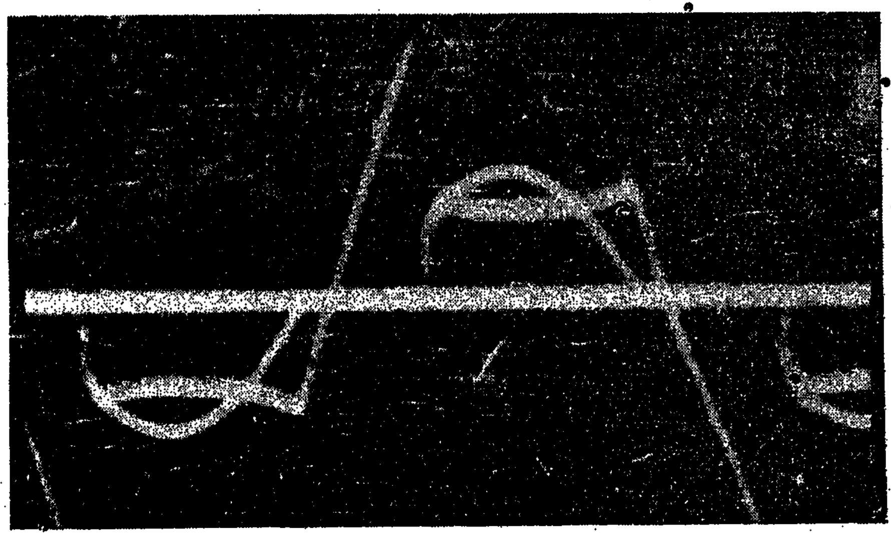

Fig. 3. Oscillographic record of current (a) in and voltage (b) across a section of neon tubing with current limited by resistance

Considering again the circuit which has wave form characteristics as indicated in Fig. 6, suppose the initial condition is open circuit, when only the voltage $e_s$ exists; then let a load suddenly be applied and, for simplicity, assume that no oscillatory phenomena are involved. The terminal voltage must change from the open circuit wave form to the load voltage wave form which requires not only a change in magnitude, but also a change in phase relation.

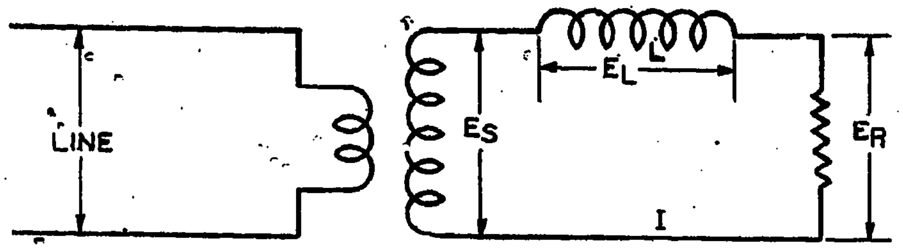

Fig. 4. Circuit diagram of a high reactance transformer with leakage reactance concentrated in a series inductance (L)

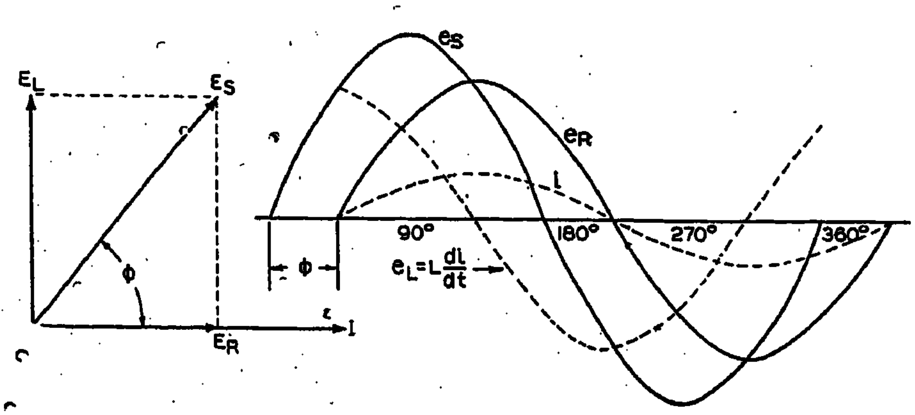

Fig. 5. Vector (left) and wave form (right) diagrams showing the relation of voltages for a high reactance transformer supplying a resistance load

Likewise, when the load is removed suddenly the voltage must transfer from the load voltage condition to that of open circuit voltage wave form. The terminal voltage will follow some form as generally indicated in Fig. 7. By further reference to Fig. 3 it is evident that, since the current is zero for an appreciable time during each half-cycle, the load is equivalent to one which is applied and removed at the beginning and end of every half-cycle.

Now, the general wave form of voltage across the terminals of a neon tube may be derived. If it be assumed that the neon tube load is applied to the transformer at the instant when $e_s$ crosses the zero axis the voltage will rise along the open circuit wave until ionization occurs. After this value of voltage is reached the flow of current causes the voltage to drop rapidly to the load voltage wave form. This rapid decrease in voltage causes the current through the neon gas to increase to a greater amount; but an instant later the voltage will rise along the load voltage wave form, which rise must be accompanied by a decrease in current through the neon gas. This process is contrary to the normal tendencies of the current, which attempts to maintain a sinusoidal wave form. From the standpoint of eqs 1 and 4, the current flow during the initial portion of each half-cycle will not satisfy both these equations because of this unstable phenomenon which causes the voltage and current to continue to oscillate until finally a stable state is maintained. This general process is shown in Fig. 8. At the end of each half-cycle the load is removed and hence the voltage returns to the open circuit position which by this time already has crossed the axis and may be of sufficient magnitude in the opposite direction to cause instant reionization of the gas for the next half-cycle. In Fig. 9 is shown a cathode ray oscillogram of the unstable portion of a half-cycle. From this oscillogram one may come to the conclusion that the oscillatory period is similar to a damped oscillation which finally terminates in a stable condition.

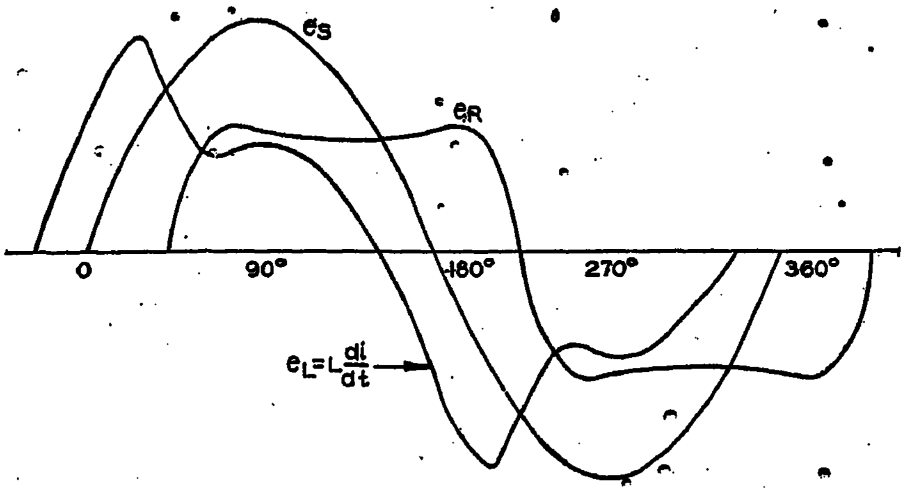

Fig. 6. Voltage wave forms for a high reactance transformer supplying a load requiring a peaked current wave

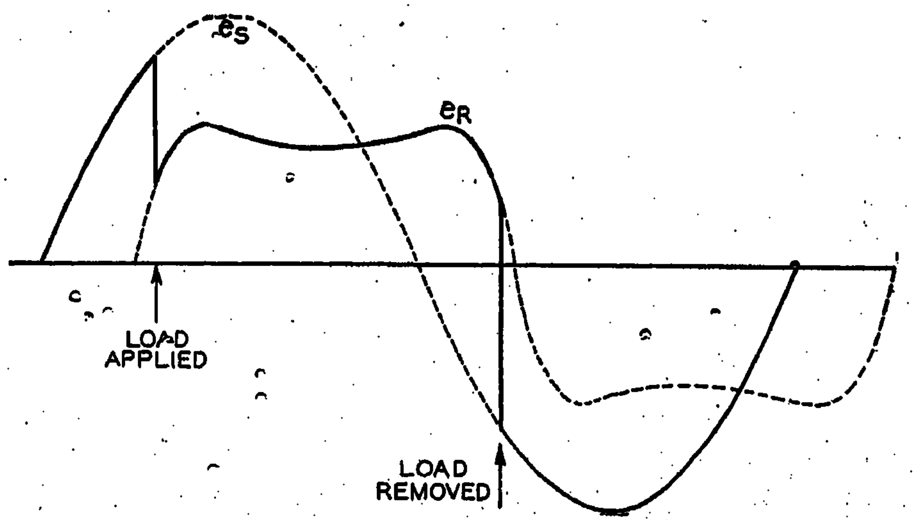

Fig. 7. Voltage wave form for a high reactance transformer supplying an intermittent load requiring a peaked current wave

When the length of tubing is increased the position of $e_i$ in Fig. 8 and the ionizing potential shift to a higher value. It is possible to add such a length of tubing that at no time during the half-cycle will the current satisfy eqs 1 and 4, and the result is a continued oscillation throughout the entire half-cycle. This unstable phenomenon is accompanied by the appearance of a series of dark spaces (referred to as "beads") in the illumination emitted by the neon gas. By still further increasing the length of tubing the ionization potential may be increased to a value corresponding to the maximum value of the open circuit voltage wave. Occasionally this open circuit voltage may be insufficient to produce ionization, and for an entire half-cycle or longer no illumination will be produced. Such a condition is the cause of flicker. During this period the voltage simply follows the open circuit wave form until ionization is produced again, which may or may not be on the next succeeding half-cycle. In Fig. 10 is shown an oscillogram, made with a mechanical oscillograph, that represents the wave form of voltage showing 3 conditions: flicker, beads, and stable operation. A wave representing what the open circuit voltage would be if there were no tubing connected to the transformer also is shown on the oscillogram. Too great a length of tubing places a severe strain on the transformer, especially if beads occur, because the high frequency oscillations are prolonged for an entire half-cycle and the peaks of these oscillations are near the peak of the open circuit voltage wave form.

Occasionally it happens that one user of a neon sign obtains better performance than another having the same type of transformer and the same kind and length of tubing. This difference in operation may be explained by the fact that the amount of capacitance from the tubing to ground may be different in the 2 installations. When a capacitor is placed across the terminals of a high reactance transformer the voltage is raised above the open circuit value. If the capacity is small, however, the amount of boost in voltage is small on open circuit, but with a neon tube load this capacitance is effective. The reason for this is that the rapid change in voltage at the end of each half-cycle, as shown in Fig. 8, is equivalent to a very high frequency under the influence of which the capacitor becomes effective in boosting this peak above the open circuit value. This is especially true for long lengths of tubing for which the ionization potential is near the peak of the open circuit voltage. By purposely adding capacity to the circuit, a greater length of tubing can be operated from a given transformer, but this is because the voltage rises above the open circuit voltage at the beginning of each half-cycle and therefore is undesirable from a standpoint of transformer life. To obtain successful operation from the transformer as well as from the neon tubing it is essential to operate the transformer with a length of tubing considerably shorter than that which will produce flicker or beads.

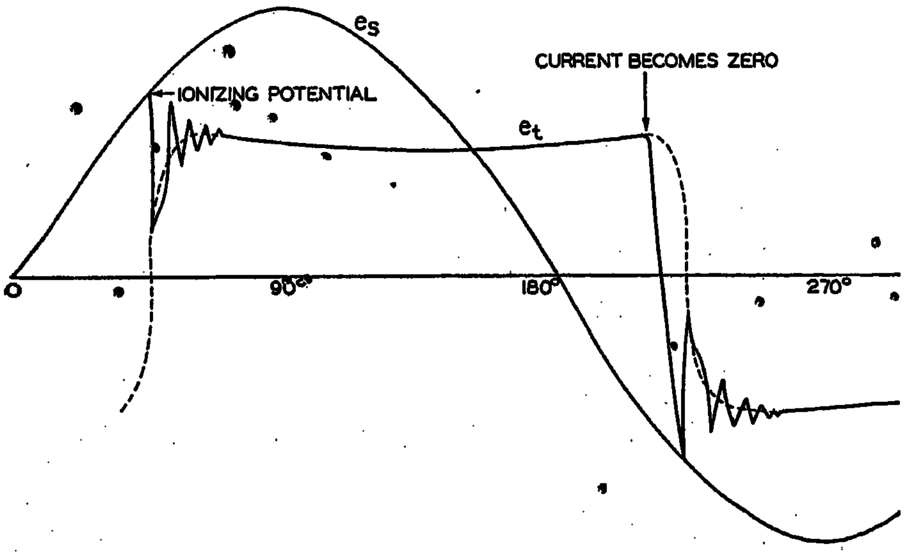

Fig. 8. Wave form of the load voltage across a neon tube

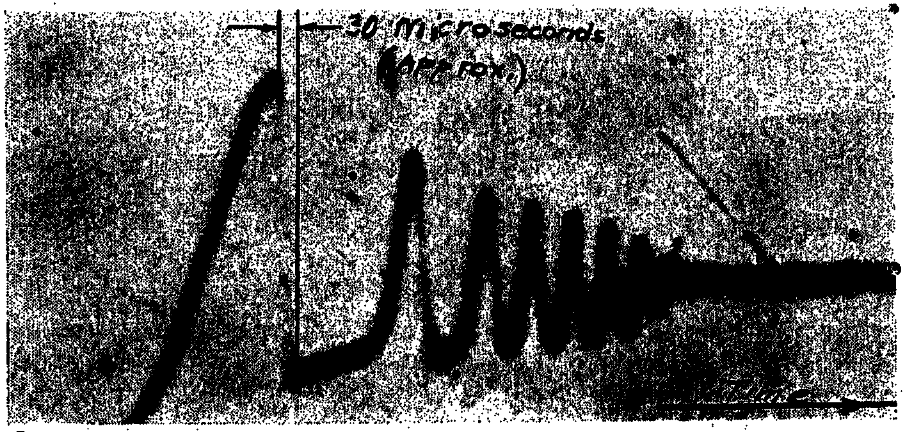

Fig. 9. A cathode ray oscillogram of a portion of one half-cycle of a neon tube voltage wave showing how the unstable portion is attenuated

Some of the most important factors affecting the operation of a neon lighting system arise from the characteristics of the tubing itself. Such factors as gas pressure; impurities in the gas; size, shape, and number of electrodes; diameter of tubing; and kinds of gases used to produce various colors have some influence upon the ionizing potential of a given length of tubing and upon the shape of its volt-ampere characteristic curve. One may realize that a change in the shape of the curve of Fig. 1 will influence eq 1; hence the duration of the unstable period of each half-cycle, and the magnitude and frequency of the oscillations during this period, will be different for each different type of tubing. A transformer of some specific rating may operate 70 ft of one type of tubing, whereas the same transformer might be under a more severe strain if loaded with only 40 ft of some different type of tubing, because of the possible occurrence of high frequency oscillations and of peaks higher than the open circuit voltage.

In the foregoing discussion many factors have not been considered; such as change in ionization potential with temperature of electrode, change in volt-ampere characteristics with temperature, deionization time of neon gas and others. No doubt many of these items should be taken into consideration in order to offer a complete explanation of the wave forms of voltage and current observed. However, the important point to bear in mind is that a study of the voltage and current wave forms of neon tubing presents a much clearer picture of the physical operation of this system of illumination than otherwise would be possible.

# Experience With Supervisory Control

**The Reading-Philadelphia suburban electrification has afforded a thorough trial of supervisory control equipment in actual operation. The experiences which have been secured with this equipment and which demonstrate its numerous advantages are described in this article.**

By
J. E. PASTORET
ASSOCIATE A.I.E.E.
Reading Company,
Philadelphia, Pa.

ALL substations and switching stations for the Reading-Philadelphia suburban electrification are non-attended and operated by supervisory control. This type of control was selected on the basis of flexibility, speed with which the system can be cleared at the time of fault, freedom from error, concentration of operation at one point, elimination of divided responsibility, and economy. Two men maintain the equipment which is installed in 21 stations. There has been no trouble experienced from induction, no faulty operations have been performed, no faulty indications have been given and not a single train delay has been caused by failure of the supervisory control equipment. Each benefit attributed to the equipment has been fully realized in operation, proving the adequacy of supervisory control for operating an electrified railway.

The power dispatcher's office is located at Wayne Junction, 5 miles from Reading Terminal, Philadelphia, Pa., as this is the junction of several branch lines and the location of the railroad's main substation. Here also, is the Philadelphia Electric Company's frequency-changer station which supplies the 25-cycle power for the electrification. Train dispatchers are located at Reading Terminal and a special telephone line connects the train dispatcher's office with the power dispatcher's office.

From his office at Wayne Junction the power dispatcher operates the entire system with supervisory control; he controls 8 main substations and 13 switching stations, including control and supervision of 255 points over 4 supervisory control systems, utilizing 4 sets of line wires. Table I indicates the various systems and summarizes the number of stations and control points on each set of line wires, one set of line wires being required for each system. It is of particular interest to note that on the Wayne Junction-Lansdale system there are 11 stations, all operated over the same set of line wires.

### Table I—Summary of Supervisory Control Equipment

| Station | Number of Points | Dist. from Disp. Office (Miles) |
|---|---|---|
| System A—Wayne Junction to Reading Terminal—Westinghouse "Visicode" | | |
| Race Street | 24 | 5.3 |
| *Reading Terminal | 6 | 5.0 |

* Transformer substation.
** Equipment under construction.

The supervisory control systems provide the dispatcher with the following operating features:

1. Control and indication on all circuit breakers and motor-operated trolley sectionalizing switches.
2. When an automatic operation occurs, an alarm bell is sounded, proper indication of the position of the unit is given, and a disagreement lamp indicates which unit has operated.
3. An alarm is sounded and an indication is given if any substation battery voltage reaches a predetermined low value; indication is also given when the battery voltage returns to normal.
4. An alarm is sounded and an indication is given if the temperature of any power transformer on the system reaches a predetermined high value; indication is also given when the temperature returns to a safe operating value.
5. All substation bus differential lockout relays are electrically reset by supervisory control.

## OPERATING EXPERIENCE

In the first 6 months of operation there have been several cases of low battery voltage indicated; in each case a maintenance man was sent to the station to make repairs and no serious trouble developed.

During the same period there was one bus differential relay operation which appeared to have been faulty. This occurred during the morning rush hour. The power dispatcher reset the lockout relays and reclosed the breakers, all of which re-

---

Full text of "Operating Experience With Supervisory Control on the Reading-Philadelphia Suburban Electrification" (No. 32M14) presented at the A.I.E.E. summer convention, Cleveland, Ohio, June 20-24, 1932.

ained closed. No train delays were involved. On he other hand, had it been necessary to send a man o the station, serious train delays would have een caused at a most strategic hour.

The line wires are carried in a jute armored comunication cable installed along the railroad rightf-way, which is used jointly for railroad telephone nd telegraph circuits and supervisory control. To uard against line wire trouble a completely conected spare set of line wires has been provided for ach system and the power dispatcher can transfer rom one set to the other by merely pressing a button r throwing a switch on the control desk. There ave been no cable failures; however, several cases f open line wires have occurred due to poor conections to terminals but there has been no time uring which trouble was experienced on both sets f line wires simultaneously.

A thorough study was made to determine the ffect of induction upon the operation of the superisory control equipment, also of methods of drainng the induced current. On the 2-wire "visicode" ystems the drainage consists of a resistance conected between each line wire and ground and on the -wire "synchronous selector" system a resonant rain is employed, consisting of a condenser in series vith a reactor connected between each line wire and ground. In both systems, vacuum type protector ubes which are self-recovering when the high voltage is reduced, protect the line wires from voltage n excess of 300 volts caused by a cross with a high voltage circuit, from lightning or from an exceedingly severe short circuit. Fuses and carbon type protector blocks used on the railroad telephone and telegraph lines are not used on the supervisory control line wires in order to eliminate the possibility of open circuits and grounds. Operating experience has indicated that the drainage employed is adequate and that there have been no failures caused by induction.

## INSTALLATION, TESTING, AND MAINTENANCE

Installation and testing of the supervisory control equipment offered no serious problems, the entire installation being carried out by the Reading Company's electrification forces. There were a few minor difficulties encountered during the testing period, such as trouble from blown fuses and necessity for readjusting relays which were altered during shipment. Tests consisting of load and short-circuit induction were conducted to determine the efficacy of the drainage equipment. Load induction was simulated by tying the trolley to the rail at the end of the line. The voltage then was raised until the desired current was circulating. Current up to 1,500 amperes was stub fed over 14 miles of trolley rail circuit, and no difficulties in the operation of the supervisory control equipment were experienced. Further, no trouble occurred when full-voltage short circuits were applied at the end of the line fed in the same manner. Following the induction test, power system tests were conducted throughout the entire electrification territory and whenever possible test setups were made by the power dispatcher with supervisory control and all indication of circuit breaker operations given by the supervisory control were checked. Any difficulties arising were immediately analyzed and corrected. The thoroughness of the tests applied prior to the starting of revenue service undoubtedly has helped to effect the creditable operation of the equipment.

At an early date it was realized that the maintenance of the supervisory control equipment would require a skilled man capable of tracing the circuits and adjusting telephone type relays. The railway company employed a man and gave him every opportunity to become thoroughly familiar with the equipment. He remained at the factory during its construction and inspection, following closely the installation and finally the testing. Since the entire system operation is dependent upon the operation of the supervisory control equipment, proper provision for the maintenance of this equipment warranted special consideration. Just after the starting of revenue service, a second man familiar with telephone type relays, was employed as a helper, since it was felt that one man should be available at all times in case of emergency.

The routine maintenance of the supervisory control equipment requires 50 per cent of the

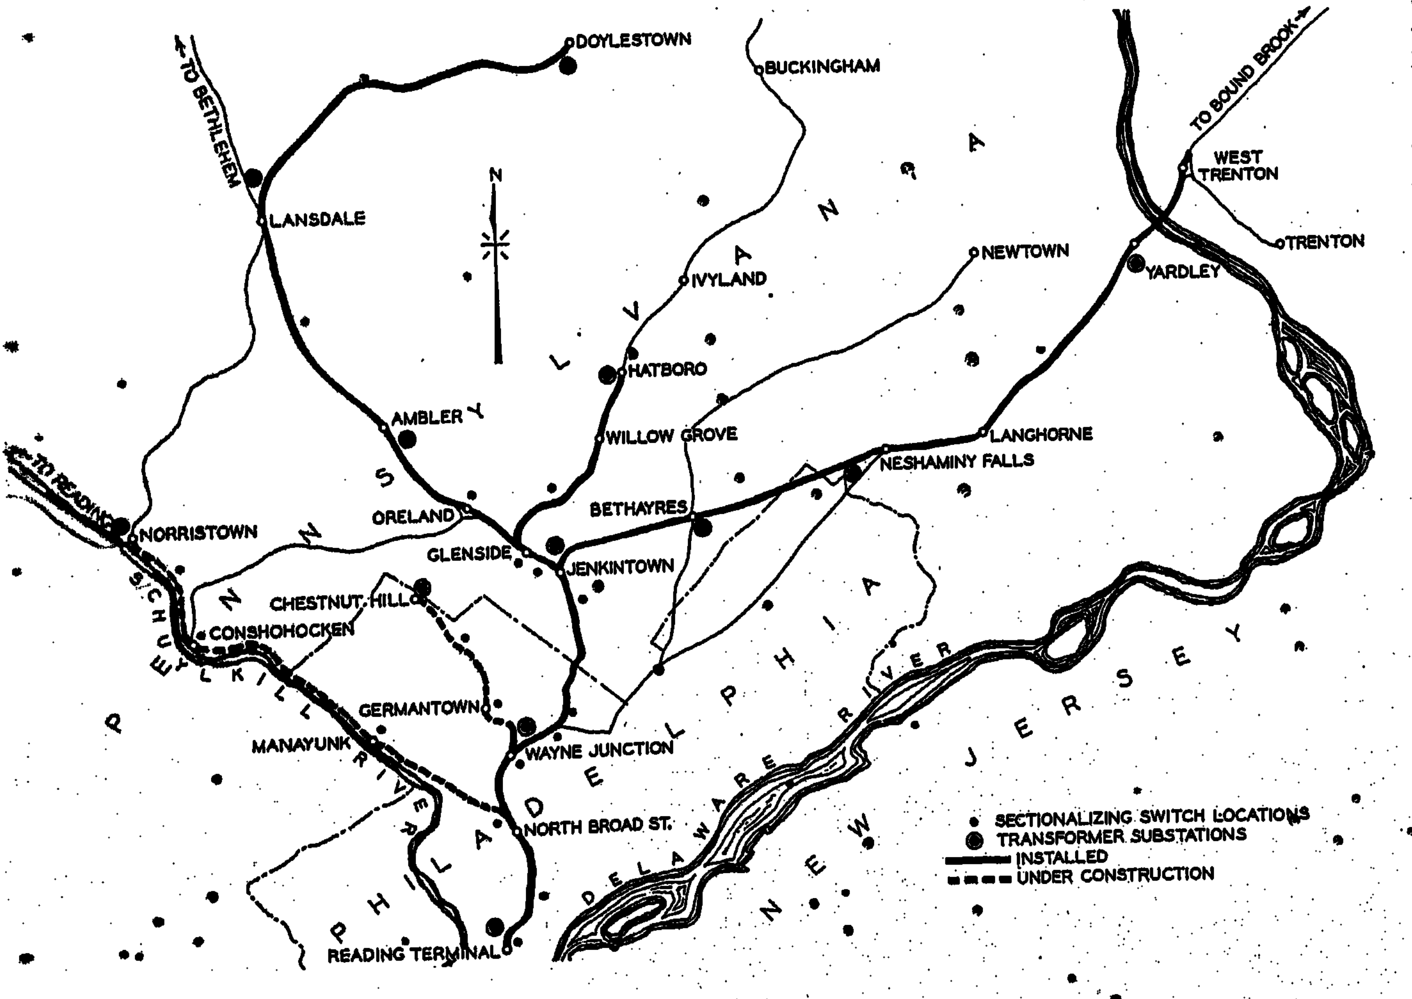

**Fig. 1.** The Reading-Philadelphia suburban electrification, to which supervisory control has been applied

time of 2 men, the remainder of their time being spent on general substation maintenance. The following supervisory inspection schedule is in effect:

1. Two-week Inspection:
    - Check of batteries
    - Check of charging equipment and charging rate
    - General inspection of relays
2. Three-month Inspection:
    - Detailed inspection of all equipment
    - Clean relay contacts
    - Adjust relay contacts
    - Check all moving parts
    - Calibrate voltage-indication relays

Once each week the power dispatcher operates every device including the opening and reclosing of each circuit breaker and motor-operated trolley sectionalizing-switch on the system. This procedure not only checks the supervisory control equipment but also checks the closing and tripping circuits together with the mechanisms of all devices. Close contact is maintained between the operating force and the engineering department. The power dispatcher's daily reports include supervisory control failures, together with their cause if known. In addition, a monthly report of supervisory control failures covering the details of each failure is compiled by the operating department. This report is analyzed, failures are classified, and a curve of monthly failures is plotted.

## RESULTS

The first 6 months of operation represents 126 station-months; 35,000 operations were performed and 35 failures occurred, or 1 failure per 1,000 operations. Of the 35 failures, 11 were due to interposing relays, 6 were caused by blown fuses, and 18 by failure of supervisory control twist keys and relays.

In many cases the constant visual indication given by the system diagram on the control board has provided the power dispatcher with the necessary information enabling him to think logically, clearly, and rapidly at the time of trouble. This resulted in the restoration of power in a minimum amount of time, thus reducing the time of train delays. The advantage of eliminating divided responsibility and possibility of error in communicating orders is borne out in the fact that not a single faulty switching operation has been performed. No operations not initiated by the power dispatcher were performed by the equipment.

Although its performance has been good, it must be recognized that supervisory control has not reached a final stage of perfection. The equipment can be improved by further eliminating the possibility of failures. Systems where line wires loop through stations are undesirable when several stations are operated over the same set of line wires, since a fault in one station renders all stations inoperative. With the present system in which stations are operated in parallel across line wires, certain troubles tie up the entire system. However, by disconnecting the faulty station the remainder of the system can be operated. It may be possible that a scheme for automatically disconnecting the faulty station can be developed. High speed, together with a minimum number of line wires, is desirable.

---

# Oxid Coatings on Aluminum

**Although possessing great affinity for oxygen, aluminum has the unique property of being able to protect itself from corrosion by forming on its surface a hard, thin, and almost invisible oxid coating. Characteristics of this film and some of its many uses are described in this article.**

By

J. D. EDWARDS MARTIN TOSTERUD

H. K. WORK

All of the Aluminum Company of America, New Kensington, Pa.

INTEREST in oxid coatings on aluminum began with the discovery of the metal about 100 years ago, as the chemical attraction of aluminum for oxygen is one of the most important characteristics of the metal. At various times in the history of aluminum, attention has been focused upon the oxid film, from the scientific standpoint or from the commercial standpoint. To the scientist the electrical characteristics of the oxid film have been of great theoretical interest and for many years have been the subject of experimental study and speculation. Important commercial uses of the film in various electrical devices has followed the scientific studies.

Aluminum owes its stability and resistance to corrosion to the invisible oxid film always present. Whenever exposed to air containing moisture, the metal immediately becomes coated with a film of oxid; this film ordinarily is invisible and not more than a relatively few wavelengths of light in thickness. In general the film is quite impermeable, so that pure aluminum will stand exposure to water with little corrosive action. The presence of this oxid film is quite apparent when one attempts to amalgamate aluminum. Aluminum and mercury combine readily, but when covered by an oxid film the mercury will not wet the aluminum and hence will not combine with it. Even if the aluminum is freshly abraded, as by filing or scratching, and then plunged into mercury, no action takes place because the oxid film reforms instantly. If, however, the oxid film is removed by abrasion while immersed in the mercury and out of contact with air, amalgamation takes place.

A highly important characteristic of this oxid film is its impermeability. Oxid formed from

---

Full text of a paper "Oxid Coatings on Aluminum" (No. 32-78) presented at the A.I.E.E. summer convention, Cleveland, Ohio, June 20–24, 1932.

aluminum occupies a greater volume than the aluminum from which it is formed; apparently this results in a compact and non-porous film with great protective properties. Even on continued heating at high temperatures, the film shows relatively little increase in thickness. Although impermeable to gases, the oxid film as naturally formed has a negligible electrical insulating effect and offers little resistance to the passage of current, even at very low voltages. This is fortunate, and permits the manufacture, for example, of variable air condensers with aluminum plates held in their mountings by mechanical pressure, with no increase in resistance over similar condensers of other metals in which the plates are soldered to the supporting pillars.

The asymmetric character of the film "artificially" produced, when aluminum is made the anode in various electrolytes, has been of great scientific commercial interest. Since the rise of the radio industry, extensive use of film-coated aluminum has been made in the electrolytic rectifier and, more recently, in the electrolytic condenser. High capacity in small volume and at low cost has proved a great stimulus to the development of the electrolytic condenser. Originally marketed in the form of a cell containing electrodes immersed in a substantial volume of electrolyte, the trend for small condensers, at last, is now largely toward the so-called "dry" form, in which a limited volume of electrolyte is held absorbed in a paste kept in contact with the electrodes. In all of these devices, however, the oxid film—at least the active part—is quite thin.

## THICKER COATINGS NOW BEING USED

Extensive use of oxid coatings having thicknesses comparable with those of paint films is a relatively recent development. If aluminum is made the anode in boric acid, the potential drop at the anode may be increased to a value of about 400 to 600 volts with very little current passing; the film, once formed, is thin and shows little tendency to decrease or increase in thickness. If, however, an electrolyte of different chemical characteristics is chosen, as, for example, a dilute solution of sulphuric acid or oxalic acid, a different behavior is noted. Within limits, the oxid film may be built up to a substantial thickness, since the potential may not rise above from 10 to 50 volts, and current continues to pass until thick films have been formed, say, 0.001 in. or over. Films formed in this latter way, when removed from the electrolyte and dried, have desirable mechanical, chemical, and electrical properties. The film in respect to hardness partakes of the characteristics of corundum, which is a hard, crystalline oxid, $Al_2O_3$. Because of this hardness, it possesses wear and abrasion-resistant qualities that can be made use of commercially.

Dielectric strength of these dry films can be made sufficiently high so that the films can be used for electrical insulation on wire, sheet, and foil, to be used as conductors and in condensers, respectively. In a chemical way, the films can be made with or without high adsorptive properties, so that they can be colored by absorption of dyes or mineral pigments; this opens up a new and extensive field for obtaining decorative effects. These thick oxid films on aluminum can be obtained not only by electrolytic treatment, but also by direct chemical action of various solutions on aluminum. Properties of these thick films are discussed in succeeding paragraphs.

In the formation of oxid coatings on aluminum by electrolysis oxid is formed at the interface between the aluminum and any oxid coat already existing. It might be thought, therefore, that the oxid coat could be increased to any thickness as long as the coating remains sufficiently permeable to permit the passage of current. Another limiting factor, however, is the solvent action of the electrolyte upon the film. Most electrolytes that are useful for producing thick coatings have an appreciable solvent capacity for aluminum oxid, usually increasing with rise in temperature; thus the anodic coating process becomes a race between the oxidizing action of the current and the solvent action of the electrolyte. The oxid coating also may have its characteristics changed by specific chemical reactions with the electrolyte.

An interesting experiment with an electrolyte of low solvent action gave a series of 8 coatings which by direct measurement of microscopic sections were found to have an average thickness of 0.00038 in. Direct measurement showed also that the aluminum sheet used in the experiment had increased in thickness by 0.0002 in. as a result of oxidation on both sides, so that the increase in thickness attributable to a single oxid film is 0.0001 in. The aluminum, therefore, in forming the oxid increased in volume by about 35 per cent. This is a difficult measurement to make with precision, the values obtained ranging from about 15 to 60 per cent. When, however, electrolysis was carried out with a solution in which aluminum oxid was highly soluble, the sheet frequently showed a total decrease in thickness many times the thickness of the oxid coating, even though the coating itself was of substantial thickness.

Coatings described in the previous paragraph were subjected to X-ray examination by the powder method and were found to be amorphous—at least no evidence of crystallinity was observed. Water in the coating there probably is held by adsorption, and not as one of the crystalline hydrates of aluminum. However, by a special after-treatment the oxid can be converted, at least in part, into crystalline aluminum mono-hydrate; this change is accomplished by a marked decrease in the permeability of the film and an increase in its dielectric and protective properties.

## OXID FILM AN INSULATOR

From the standpoint of the electrical engineer, the possibility of using an oxid coat as insulation on aluminum conductors is a matter of considerable interest. The idea, of course, is quite old and has been applied commercially to some extent, particularly abroad. The present advanced technique and knowledge of oxid coatings now available has created a new interest in these coatings. In certain types of electrical machinery, the use of aluminum conductors would be advantageous from the standpoint of weight reduction. Another advantage of the oxid-coat insulation is that it is non-combustible and will withstand fairly high temperatures without deterioration. There is even a possibility of its use as a dielectric in dry condensers.

Breakdown voltage of oxid films is roughly proportional to the thickness of the film. The breakdown characteristics, however, are dependent also upon the specific physical and chemical characteristics of the film. In Fig. 1 is shown a series of observations on the breakdown voltage of oxid films on commercially pure aluminum, plotted as a function of the thickness of the oxid film. This particular film was made by anodic coating of aluminum in a 15 per cent solution of sulfuric acid at a temperature of 75 deg. fahr. To produce an oxid film 1 mil thick required a period of about 1 hr, under prevailing operating conditions. By special after-treatment, without introducing any organic material into the film such as that referred to in a previous paragraph, the breakdown voltage of the film may be increased as much as 50 per cent or more. The oxid coatings also can be produced in absorbent form, and in this condition can be impregnated with oils, waxes, or enamels; such treatment imparts to the coatings a substantial increase in insulating value.

### OXID COATING HARDER THAN BASE METAL

That the oxid coat is much harder than the base metal is at once obvious if an attempt is made to scratch the surface. Some quantitative data have been obtained by subjecting films of various thicknesses to an abrasion test consisting of abrading the surface with an aloxite wheel under light pressure. The abrasion resistance is measured in terms of the number of revolutions which the specimen makes against the abrasive wheel. These data are given in the Table I.

According to Table I, the abrasion resistance of an oxid coating increases rapidly as the thickness of the film increases beyond about 0.3 to 0.4 mil. For comparison with these figures, reference may be made to the abrasion resistance of enamel and varnish coats such as applied in finishing metal furniture and office equipment. A typical finish of this type, consisting of primer, 2 ground coats, graining coat, and 3 coats of finishing varnish, having a total thickness of 3 mils, showed an abrasion resistance of 306 revolutions; a somewhat different finish of the same thickness showed an abrasion resistance of 1,095 revolutions. For equivalent thicknesses, therefore, the oxid coat is substantially harder than the baked enamel just mentioned.

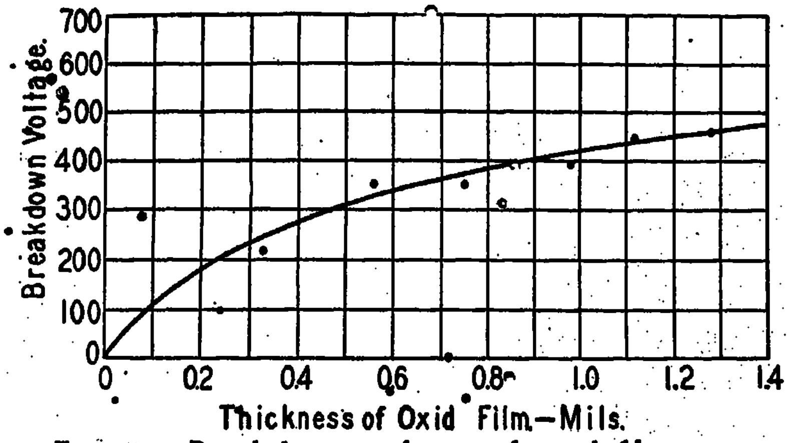

**Fig. 1. Breakdown voltage of oxid films on commercially pure aluminum**

**Table I—Abrasion Resistance of Aluminum Oxid Coatings**

| Thickness of Coating, Inches | Abrasion Resistance, Revolutions Against Aloxite Wheel |
|---|---|
| 0.00011 | 15 |
| 0.00019 | 95 |
| 0.00031 | 268 |
| 0.00037 | 365 |
| 0.00074 | 2,563 |
| 0.00148 | 7,061 |

Oxid films not over 0.1 to 0.3 mil thick on thin sheet can be formed readily into bottle caps and similar articles. These films of course crack on bending, but the cracks are so minute as to be generally undetectable except under the microscope; adhesion of the film to the metal is so firm that no flaking occurs even when these cracks are present. These minute cracks appear to have very little, if any, effect on the insulating value of the coating. In addition, tests made so far indicate that the oxid coat does not affect unfavorably the fatigue strength of the base metal.

As has been mentioned already, oxid coatings may be applied to aluminum by chemical dip methods without the use of electric current. Such coatings, while unusually relatively thin, nevertheless have been used commercially, both in the United States and abroad, for their insulating value. Because of their characteristics, such coatings are of use only when subjected to low voltages; therefore their greatest use is in motor field coils and similar applications where the voltage drop between the conductors is low.

Certain types of oxid coatings are decidedly absorbent and can be colored readily with dyes and mineral pigments. These methods of coloring the oxid coatings present interesting possibilities in the electrical industry. Wires may be colored, for example, to indicate polarity of direct current; where several wires are in a single conduit, the colors may be used to identify the various circuits. For rapid heat dissipation, busbars and other conductors may be colored black. The bottoms of aluminum utensils for use on electric stoves may be colored black for better heat absorption. Commercialization of plain and colored "alumilite" finishes in the electrical industry already is under way; oxid-coated and colored nameplates are finding increasing use; a tremendous number of aluminum flashlight cases in attractive colors has been manufactured. Furthermore, practically the entire electric refrigerator industry has turned to the use of aluminum refrigerator trays and grids with plain anodic coating. It is quite evident that these finishes will be of increasing value to the electrical industry in the future.

# A Bridge Method of Testing Welds

**A new non-destructive method of testing welds by an electrical means has been developed which can be applied to welds made in the field as well as to those made in the shop. A reliability of 8 out of 9 welds tested, or 89 per cent, already has been obtained and gives good promise for the future. The method may be applied also to the finding of flaws in other homogeneous objects of magnetic materials.**

By
J. R. BATCHELLER
ENROLLED STUDENT A.I.E.E.
Portland, Ore.

SINCE the advent of welding there has been an ever-growing demand for a simple and satisfactory non-destructive test for completed welds. Several schemes have been devised and used successfully in the experimental laboratory and in the shop. Among these are (1) the stethoscope method, (2) the X-ray method, and (3) various electrical and magnetic methods.

Of these systems the X-ray method and one of the electrical methods have been successfully used in the routine production testing of welded boilers at the Babcock and Wilcox boiler works. Both of these systems, however, are chiefly limited to shop use, and are not readily adapted to the conditions of field work.

It has been suggested that a satisfactory non-destructive testing device should possess the following 3 characteristics: first, the device must be portable; second, it must give instrumental indication of flaws; and third, it must give instrumental indication of the relative strength of the weld as compared with the stock from which it was made. Thus the ultimate goal to be achieved was set, and constantly kept in mind as the work progressed. After due consideration, it was believed that an a-c bridge with a visual balance indicator offered the greatest possibilities.

## THEORY OF THE TEST

It is well known that the inductance and the effective resistance of a coil which has an iron core depend upon the magnetic circuit. Therefore if an air-gap is introduced into that magnetic circuit, then the inductance and effective resistance have new values. This is the basis upon which the bridge method of testing welds operates.

The most satisfactory method of measuring the inductance and effective resistance of a coil is by some form of impedance bridge. In the preliminary tests, an exploring device similar to that shown in Fig. 1 was constructed and connected to an impedance bridge which was available. This particular bridge did not give good results. Investigation of the theory of its operation showed that for measuring inductance it was a comparison bridge and the least accurate of the general types of the impedance bridge. In the comparison bridge the calibrated standard is the same as the unknown; that is, a standard inductance is used for measuring an unknown inductance and a standard condenser for measuring an unknown condenser. This type of bridge is difficult to balance with very great accuracy. The resonance bridge gives a much more sharply defined balance point and is therefore much more accurate. It makes use of a standard condenser to measure an unknown inductance and a standard inductance to measure an unknown condenser. A series resonance bridge therefore was constructed for making the measurements of the change in the inductance and the effective resistance of the exploring device.

## DESCRIPTION OF APPARATUS

The complete equipment which finally was developed is shown in Fig. 3, the schematic diagram being shown in Fig. 4. The equipment consists of 4 major parts:

1. The oscillator which supplies the alternating current for the operation of the bridge.
2. The bridge by which the measurements are made.
3. The exploring device for examining the weld.
4. The balance indicator which shows the condition of the weld.

The oscillator consists of a single tube with inductive coupling between the plate and grid, and with a transformer in the plate circuit for obtaining the output. The variable condenser shown connected across the grid coil controls the frequency. The low pass filter section was used to eliminate the harmonics from the oscillator output.

In the impedance bridge $R_1$ and $R_2$ are the ratio arms of exactly equal non-inductive resistors. The variable resistance $R_3$ balances the effective resistance

Essentially full text of "A Bridge Method of Testing Welds," presented before an A.I.E.E. joint meeting of the Portland Section and Oregon State College Student Branch, at Corvallis, Ore., May 23, 1931. This paper, written while the author was a senior in electrical engineering at Oregon State College, was awarded the Institute's 1931 national prize for Branch paper.

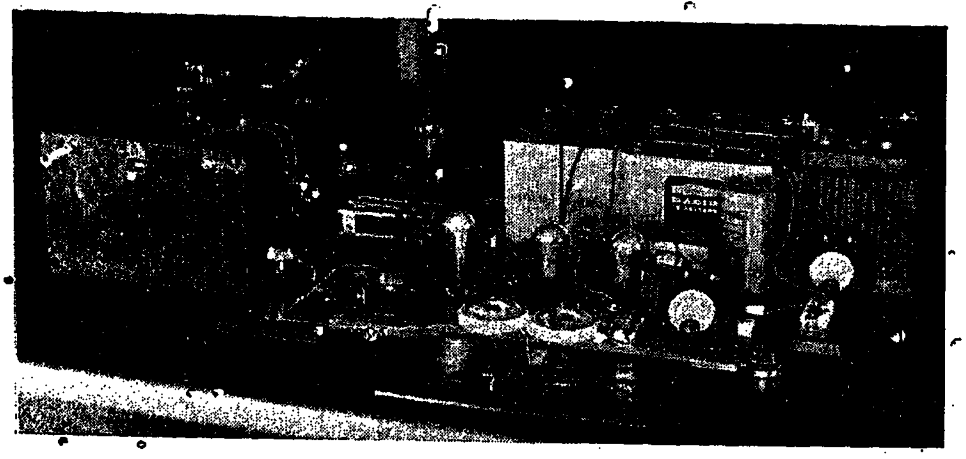

Fig. 3. Complete laboratory equipment used in test

of the exploring device. The condenser *C* balances out the inductance of the exploring device. It consists of several fixed condensers in parallel with the standard variable air condenser.

The exploring device consists of 2 coils each of many turns of fine wire wound on the 2 legs of a *U*-shaped magnetic circuit, the magnetic circuit being closed by the weld under test as shown in Fig. 1.

The balance indicator is the most complicated of the 4 parts which make up the equipment. It is a very sensitive vacuum-tube voltmeter. This high sensitivity is obtained by means of the amplifier which is composed of the 3 transformers and the first 2 tubes shown in Fig. 3. The first of these is a *UX*240 with an amplification factor of 30; and the second, a *UX*201-*A* with an amplification factor of 8. This amplifier has a voltage gain of approximately 20,000 to 1. The detector tube is a *UX*201-*A* with the milliammeter shown in Fig. 2 in the plate circuit and shunted by a large condenser, and the plate battery to bypass any unrectified alternating current. The milliammeter was provided with a shunt *S* to increase its range to 10 times full scale value during the preliminary balancing and when first energizing the tube filaments. Also a high variable resistance in series with a single dry cell was connected as shown in Fig. 4 so that it sent a current through the milliammeter in the reverse direction to that of the tube. By this means it was possible to make the voltmeter read zero when there was no voltage impressed across its terminals, and the steady plate current reading could be removed from the instrument.

A vacuum-tube voltmeter was used for 2 reasons: first, it required almost no power from the bridge for its operation as would a thermocouple or ordinary voltmeter; and second, it was much more sensitive and had a uniform scale. The minimum sensitivity was $1^1/_4$ mv. Each succeeding millivolt up to about 4, which was as high as the calibration was carried, caused an increase in the deflection of about 0.10 ma. At these low values the calibration curve was not always a straight line but followed the tube characteristic.

## METHOD OF MAKING THE TESTS

Rated current was maintained in the tube filaments at all times by the aid of the filament ammeter shown in front of the right hand storage battery in Fig. 3. The oscillator filament ammeter does not show plainly but was very important in keeping the output at a constant level. The reverse current then was adjusted so that with the voltmeter terminals open and the shunt removed the milliammeter had a reading of 0.10 which hereafter will be used arbitrarily as 1.0, thus increasing each reading to a whole number for each 0.1 ma of current.

The shunt switch then was closed again to protect the milliammeter, and the output of the bridge was connected to the voltmeter by closing the switch shown just behind the first tube in Fig. 3. Then the exploring device was placed on the stock near the weld, but not across it, and the bridge brought into balance by adjusting the variable air condenser and the variable resistor shown beside it. A balance was shown by a minimum reading of the voltmeter. When the reading was as near zero as possible the shunt was removed by opening the switch (the handle of which shows from behind the milliammeter) thus greatly increasing the sensitivity. The final balance then was obtained and the reading arbitrarily made exactly 1.0 by means of the reverse current control resistor which is shown beside the milliammeter in Fig. 3.

The exploring device then was slid along the plate to see that the balance was correct and that there was no very marked change in the indicator reading. The shunting switch was then closed and the exploring device placed over the weld as in Fig. 1. If the deflection indicated that the reading would not be off scale the shunting switch was opened and the exploring device moved along the weld, while the operator observed the indicator reading.

If the weld was as good as the stock from which it was made, then the bridge balance would be undisturbed and the reading was the same as it had been over the stock, or 1.0; but if there was a blow hole or burned place in the weld this would unbalance the bridge by changing the inductance and effective resistance of the exploring device. This flaw was indicated by an increase in the reading to 2.1 or some other value as the exploring device passed over the flaw. Also a note was made of the percentage of the width of the weld for which this high reading existed; this together with the lowest reading over the weld formed the basis for computing the efficiency of the weld. To take an actual example; the reading with the exploring device over the stock was 1.0, the minimum reading over the weld was 1.7, and the maximum reading was 2.0 for 60 per cent of the

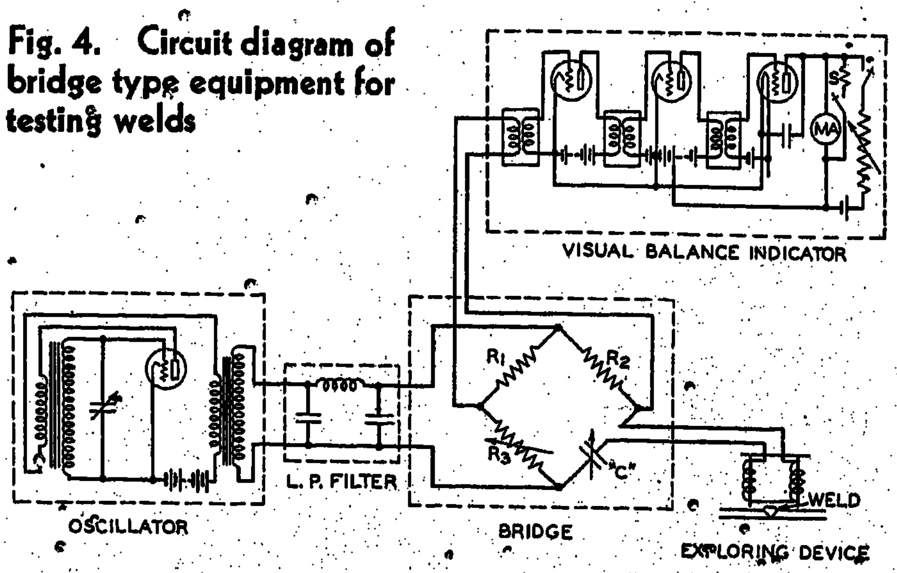

Fig. 4. Circuit diagram of bridge type equipment for testing welds

width of the weld. The efficiency was computed as the reading over the stock divided by the reading over the weld, or for the maximum efficiency 1.0 divided by 1.7 or 59 per cent, and for the minimum efficiency 1.0 divided by 2.0 or 50 per cent. But this lower efficiency was present for 60 per cent of the weld; therefore the true efficiency was 60 per cent of the way from 59 per cent toward 50 per cent, or 54 per cent for the weighted efficiency of the weld.

Before making the tests the loose scale and the splatter were removed by rubbing lightly with a piece of emery cloth. This was done because these small globules prevented smoothly sliding the exploring device along and gave false indications when they touched the pole pieces.

### Results Obtained

Through the months of January and February, 1931, about 18 welds made by students were available each week for testing. These were tested by the bridge method and their efficiencies calculated as explained. These welds then were tested in tension to obtain an actual breaking load for each one. During nearly every week some one of the specimens failed in the stock instead of in the weld, and the load at which that failure occurred was used as the strength of the stock for that week in computing the actual efficiencies. These actual efficiencies were computed by dividing the load at which the weld failed by the load at which the stock failed, because all of the welds were made from $^1/_4$ x 2 in. stock and except for slight irregularities in the stock due to rolling, had the same area.

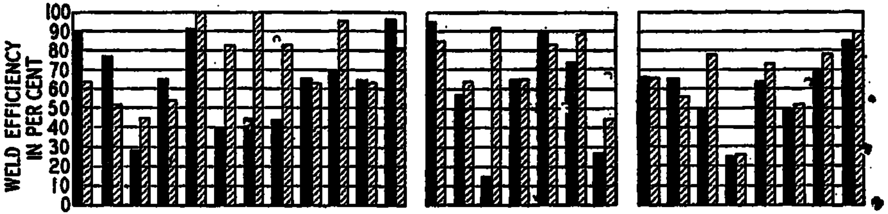
The results of tests upon an early group of specimens from which the scale was not removed are shown in Fig. 5. At that time there were no copper legs on the exploring device, heavy paper being laid on the stock to give a smooth surface. In the next series of tests, the results of which are shown in Fig. 6, the scale and globules were removed from the welds with emery cloth, but paper was still used on which to slide the exploring device.

After the exploring device was equipped with copper legs as shown in Fig. 1, another group of welds was tested and retested until results could be duplicated readily to within 1 or 2 per cent. These welds were then tested in tension; the results are shown in Fig. 7.

### Discussion of Results

Even the first group of welds tested showed a tendency for the efficiency calculated from the bridge readings to follow the efficiencies found in the actual destructive tests. After the bridge testing technique was improved the results increased in reliability. For the group of Fig. 5 the reliability was 33 per cent; for the group of Fig. 6 it increased to 57 per cent; and for the group tested after the copper legs had been added and the paper eliminated, Fig. 7 shows that the reliability jumped to 89 per cent, which is most gratifying. This shows rather conclusively that the basic theory is sound and that the errors which occurred were due to imperfect apparatus and not to theory; for as the quality of the apparatus increased, so did the reliability of the tests.

In every change in the apparatus the 3 desirable characteristics were kept in mind and are fully met by the method. As to the first, portability, while the laboratory outfit used for the present series of tests is not exactly portable, nevertheless, there is no reason why both the space required and the weight cannot be very greatly reduced. The matter of small size can be accomplished readily by the proper choice of equipment. All of the parts except the batteries and the exploring device could be assembled in a box about one-half the size of the standard condenser shown at the left in Fig. 3. The matter of battery weight also can be controlled by using the very small sized light-weight batteries. The bridge method meets the second requirement; namely, that the indications be visual. It also meets the third requirement that the readings show a direct comparison with the stock.



**Figs. 5, 6, and 7. Results of early tests (left) before scale was removed from specimen; results obtained (middle) after removing scale; and later tests (right) after copper legs were used on exploring device and without paper laid on stock**

Efficiencies as obtained by the bridge method are shown as solid bars, and actual efficiencies from tension tests as the shaded bars

The exploring device shown in Fig. 1 was developed for testing single *V* butt welds, but can be modified for use in testing other kinds of welds. One design for reaching into corners is to bend the crossarm connecting the 2 pole pieces until the pole pieces form a right angle and one of them rides on each side of the angle. Another is to still keep the *U*-shape but to make the ends of the pole piece hemispherical in shape, so that when they are placed in the angle they still make as good contact as they did on the flat plate. An offset in the connecting crossarm which would allow one pole piece to operate at a lower level than the other would make it possible to test fillet welds when one piece of stock was placed on top of the other to form a lap weld.

Also it may be desirable to replace the long copper skid with 2 wheels and the short one with 1 wheel, all of non-magnetic material. It would still be necessary to remove the splatter since if rough spots come in contact with the pole piece the balance is disturbed.

The results obtained by this method are most promising; the reliability was increased with each improvement until with a slightly more stable oscillator and a suitable period for the tubes to become stable the results should be very satisfactory. This method does not involve the use of large currents and can be made self-contained and independent of outside power supply.

# Carrier Application to a Telegraph Plant

**Carrier communication has been found to provide an economical means of conveying not only telephonic but also telegraphic information. This article describes the transmission and equipment features of a 10-channel system recently developed for 4-wire operation in a strictly telegraph plant, and includes performance characteristics showing capabilities of the system.**

Burkholder and Kelley, communication engineers, New York and Toronto

USE OF CARRIER SYSTEMS has been rapidly increasing for the last 10 or more years in the wire communication networks of this and foreign countries. To a large extent, this is due to the economies realized from the use of this means of conveying telegraphic or telephonic information, especially over relatively long distances. A gradual increase in copper costs over the early part of this period no doubt was directly responsible for the increased application of carrier systems in the communication field. However, it is noteworthy that even at present low copper costs the use of carrier still maintains a liberal margin of economy. This is due mainly to the material advancement in the carrier art which has been manifest in circuit refinements, improved performance, and simplification of equipment design, as well as improvement in the technique of coordination with the same or other types of communication facilities.

The majority of applications has been confined, primarily, to telephone plants or communication networks, employing largely metallic circuits. This is natural to expect since the design and construction of the wire and cable plant for telephone operation possess the essential transmission requirements for satisfactory carrier operation. A quite different and, in many respects, more difficult problem is encountered in introducing carrier into a strictly telegraph plant because in general the growth of present-day telegraph plants has been restricted by the wide use of d-c telegraph circuits that could be operated fairly successfully on a ground return basis. Consequently, it has not been the general practise of the telegraph companies to construct and maintain their open wire and cable circuits in a way that would provide balanced metallic circuits suitable for carrier operation. Furthermore, the operating energy levels of the various circuits on the same lead are not restricted by the presence of other types of communication circuits occupying a frequency transmission range other than that required for d-c telegraph signals. In general, this outlines the fundamental difference in the transmission problem involved in applying carrier to a telegraph plant.

Frequency indicated in hundreds of cycles per second

Other equally important factors also enter into the problem, the foremost of which is the fundamental difference in the traffic requirements imposed on the telegraph plant by the particular class of communication business handled. Telegraph service by its very nature demands great flexibility; but even greater flexibility is needed when carrier is applied. Hence it has been found desirable to provide considerable flexibility in the design of the carrier equipment itself.

## GENERAL SYSTEM REQUIREMENTS

Technical development features arising from the specific problem of designing and developing a carrier telegraph system primarily for use in the extensive domestic telegraph plant of the Postal Telegraph-Cable Company are presented in this article. This includes the performance results obtained, and a detailed description of the final standardized system.

At the time this development was undertaken, a careful study first was made of all known types of carrier telegraph systems and accepted practises employed in both the United States and in foreign countries. From this study, together with a full appreciation of the problems peculiar to adapting carrier to a telegraph plant, it was possible to set up basic requirements to be met by a carrier system capable of delivering a satisfactory quality of signal and standard of service. As a result of this investigation, the following general requirements arbitrarily were set up as an ideal to be approached:

1. Each channel of the system should be capable of handling a quality of signal commercially suitable for existing or contemplated printer operation.

---

Based upon "Carrier Application to a Telegraph Plant" presented at the A.I.E.E. winter convention, New York, N. Y., January 25–29, 1932. *Pamphlet copies not available.*

* Formerly of the International Communications Laboratories, New York, N. Y.

2. Transmission characteristics for all channels in any one particular system should be uniform, to permit unlimited interchangeability of telegraph printer facilities.

3. Transmission stability of the system should not impose any additional limitations on the operating requirements for any particular telegraph facilities used over the carrier system.

4. A unit equipment design should be employed which would embody sufficient flexibility to fulfil economically the demands of a diversified traffic growth.

5. The system should coordinate to the fullest extent with the inside and outside plants for present or future telegraph facilities of the same or different type.

Naturally, additional requirements of a more specific nature were prescribed for the initial design. These have been omitted since they do not materially relate to the subject matter of this article.

## Technical Features of Design

Having chosen suitable relays with satisfactory operating characteristics, particularly with regard to efficiency, sensitivity, and freedom from chatter and bounce, the first consideration was that of frequency band width and frequency allocation of the carriers. While the required signaling band width was well defined for the existing printer facilities, it was logical to make provision for band widths expected from contemplated future telegraph facilities under development. This led to a design of selecting circuit which could be adjusted readily to any desired band width. Details of these structures will be treated more at length later.

In reviewing all previously published information at hand, it was apparent that some variance among authorities existed in regard to the proper relation that should be sustained between signaling speed and minimum band width necessary to satisfy fundamental transmission requirements. A proportionality factor of 1.5 times twice the fundamental signaling frequency was used in determining the appropriate band width. This is in substantial agreement with prevailing practises, which specify equivalent values ranging from 1.2 to 2.0 times twice the dot frequency. Other practical considerations resulted in prescribing frequency bands wider than the theoretical value indicated, in order to provide operating margins that would insure continuity of service.

Directly related to the matter of band width is the problem of allocating the carrier frequencies. Obviously, the degree of selectivity which could be obtained economically was the essential limitation in fixing the positions of the carrier frequencies in the assigned frequency spectrum. As this system was to be the initial carrier system in an existing telegraph plant made up almost exclusively of d-c telegraph facilities occupying the lowest end of the frequency spectrum, it was natural to assign for this carrier system a frequency range immediately above, in the voice range.

It is well recognized of course that practical considerations dictate how efficiently the frequency range should be utilized. For example, the frequency space may be divided for suitable operation of start-stop printers. This would require a band width of approximately 75 cycles and would permit relatively close spacing of the carrier frequencies. For a given frequency range a given number of channels could be allocated, each of which would have an operating limit of 65 words per minute. By slightly increasing the band width to 100 cycles, it would be possible to divide this same given frequency range into a fewer number of channels, each capable of transmitting 2 channel multiplex signals with an operating capacity of 120 words per min. per carrier channel. This line of reasoning may be continued on to include 3- or 4-channel multiplex operation. While it would be possible to determine from such an analysis the best combination, from a standpoint of obtaining the greatest message capacity, in a given frequency range, it would not necessarily make the most practical use of the frequency space. The band widths finally chosen were based upon these considerations and also upon the smoothness with which carrier telegraph systems could be introduced into the telegraph plant. It appeared advisable to restrict the lowest carrier frequency to 500 cycles in order to allow ample frequency space for retaining on the same wires existing high speed d-c telegraph circuits.

Fundamental operation of all carrier telegraph systems is essentially the same. Before describing this system in detail it will be well to enumerate the principal components that go to make up any carrier telegraph system. A system comprises several individual channels, uniformly alike in make-up and normally comprised of the following essential parts:

1. A transmitting terminal consisting of frequency sources, modulators, and shaping networks.

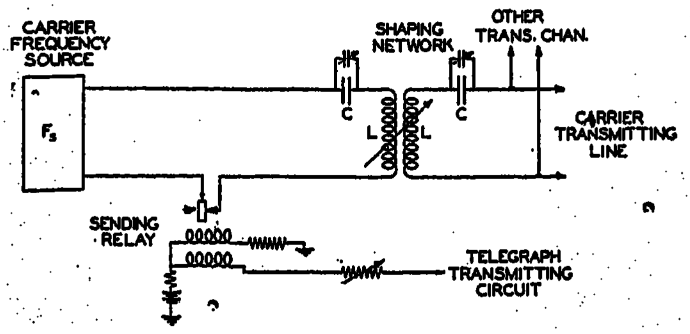

Fig. 2. Schematic diagram of transmitting channel

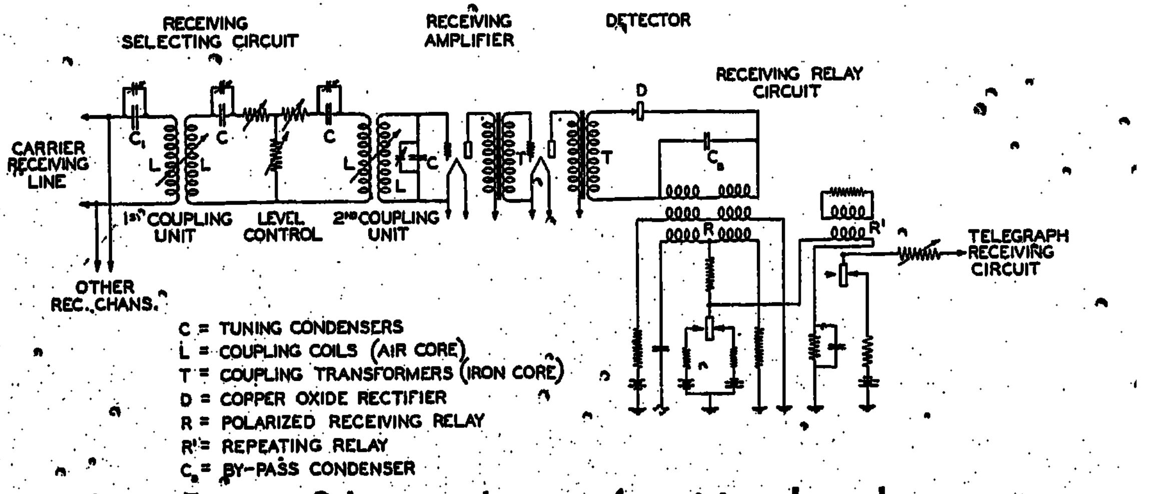

Fig. 3. Schematic diagram of receiving channel

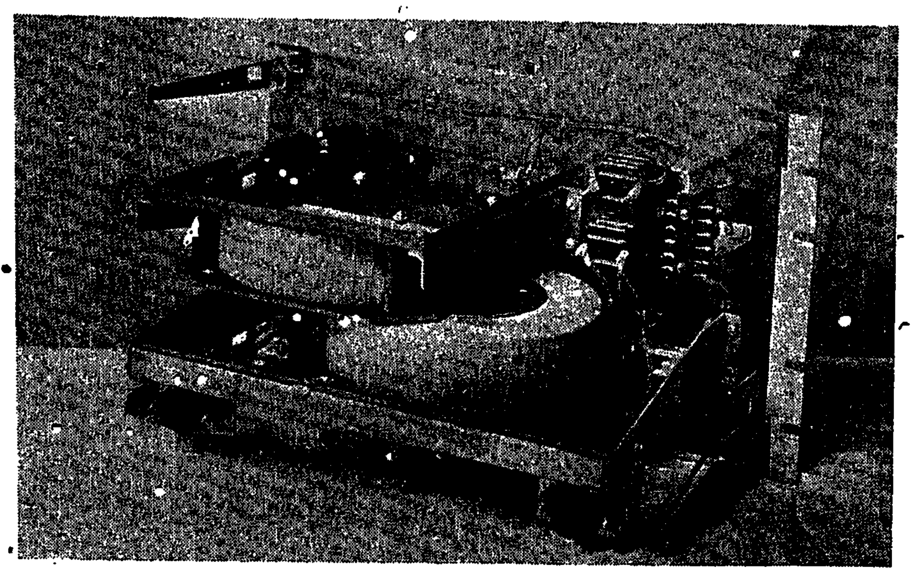

Fig. 4. Assembly of shaping network unit

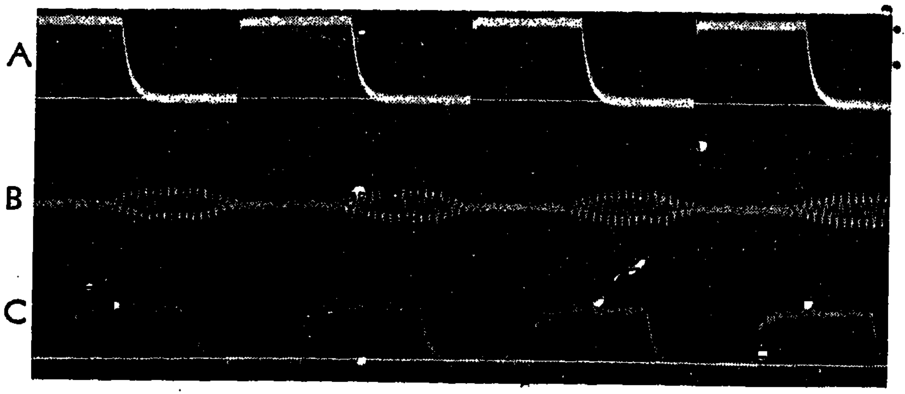

Fig. 5. Oscillogram showing over-all telegraph transmission over a typical channel

A—Signal repeated by receiving relay to receiving equipment
B—Modulated carrier current shaped for transmission
C—Originating telegraph signal received from transmitting telegraph equipment

2. Repeaters consisting of 2 separate one-way amplifiers each common to all of the channels.

3. A receiving terminal consisting of selecting circuits, amplifiers, detectors, and receiving relays.

Each tuning fork generator operates on 100 to 200 milliamperes of current from a 6-volt battery supply in common with all other generators. From each generator 60 milliwatts of power into a 600-ohm load circuit is available, if transmitting level conditions require utilizing the maximum generator outputs. Generated power output available from the multi-frequency generator at each channel frequency is 375 milliwatts into a 600-ohm load circuit. Speed control equipment associated with the unit insures a constancy of generated frequencies to within 1/4 of a per cent, for normal line voltage variations.

The purpose and functions of each of these parts already have been ably described in previous publications; therefore, the remainder of this article will be confined to a more detailed description of the apparatus developed for this particular system.

The system as a whole has been designed initially for 4-wire operation over composited open wire telegraph lines. Fig. 1 shows schematically the system layout of half of the equipment for 10 2-way carrier channels; the other half of the system obviously is identical to that part shown except that it transmits in the opposite direction.

One of the unique features incorporated in the system design was the degree of flexibility provided for satisfying the diversified use of carrier telegraph circuits, and which proved essential for meeting economically the requirements of a domestic telegraph plant. Application to existing trunk routes between important telegraph centers over which the traffic demands are heavy invariably will call for initial installations of complete 10-channel systems. At the same time, for secondary leads between less important centers, normal traffic growth may be provided for more economically by systems composed of fewer channels, due to the unit method of design. Systems consisting of from 1 to 6 channels may be equipped with individual channel frequency sources, namely, double carbon button tuning fork generators supplying carrier frequencies of 500, 700, 900, 1,100, 1,300, and 1,500 cycles per sec.; for systems requiring more than 6 channels a carrier frequency source from a multi-frequency generator supplying the following frequencies is provided: 500, 700, 900, 1,100, 1,300, 1,500, 1,700, 1,900, 2,100, and 2,300 cycles per sec.

It is readily apparent that a system design such as this is capable of being adapted to the usual communication network in an economical manner. The providing of additional channels for operating systems of 1, 2, 3, or more channels may be carried out expeditiously, without affecting the channels already in service. When a system has grown to 6 channels and additional channels are required, the individual tuning fork generators are replaced by a multi-frequency generator.

Superposition of the carrier system upon the telegraph lines is accomplished by compositing. Carrier composite sets are provided at the terminals and repeater points for restricting the carrier and d-c telegraph frequencies to their respective paths. The low frequency portion of the composite set requires a rather exacting design, as the d-c telegraph facilities operate at high speeds over the circuits employing ground return.

Telegraph line wires, which normally are untransposed for d-c operation, must be transposed to provide a suitable metallic circuit relatively free from noise or external interference for a carrier telegraph system. Loading of conductors in entrance and intermediate cables is required also, if full advantage of efficient transmission is to be realized.

## TRANSMITTING TERMINAL

In describing the transmitting and receiving channels, a description of an individual channel will suffice since all of the important units that make up the complete system are identical except for initial adjustment. A schematic diagram of a transmitting channel is shown in Fig. 2.

As previously mentioned, the carrier frequency source may be derived from either 1 or 2 different units, depending upon the number of channels making up any particular installation. Impressing the signals upon these carrier frequencies is commonly known as modulation. In carrier telegraph operation, this process may be carried out by interrupting a steady carrier frequency source in accordance with the actual signaling frequencies of the originating telegraph signals. However, in the circuit arrangements of this system, superimposing telegraph signals on the carrier by open-circuiting between the carrier generator and the shaping network, what might be termed series modulation, has proved the most satisfactory. The method is evident from the circuit shown in Fig. 2.

It has been shown very clearly by mathematical analysis, and substantiated in practise, that a relatively small portion of the side frequencies present in the telegraph signal need be transmitted over a carrier circuit. (See "Certain Factors Affecting Telegraph Speed," H. Nyquist, A.I.E.E. Jl. v. 43, p. 124; "Voice Frequency Telegraphs," W. Cruickshank, *Journal* of the I.E.E., July 1929, v. 67, No. 391, p. 813; and "The Building-Up Processes in Wave Filters," K. Kupfmuller, *Elec. Na. Tech.*, 1924, v. 1, p. 112.) The degree to which the side frequencies may be limited is dependent entirely upon the signaling speed and the signal quality that will insure satisfactory performance of the particular type of telegraph equipment used in conjunction with the carrier system.

One of the outstanding features worthy of note in the design of this system is the application of the simplest known type of selecting circuit. The familiar coupled-tuned circuit upon which the early wireless art depended for discrimination will be recognized in the shaping networks and receiving selecting circuits which form the essential parts of this carrier system development. The unique solution of the coupled tuned circuit problem by one of the authors, L. A. Kelley, has made possible a simple and convenient method for designing selecting circuits to meet any requirements for which they may be adapted. A detailed explanation of the method is presented in the article immediately following this one.

Treatment of coupled tuned circuits by this method offers a distinct advantage over existing technique for handling selecting circuit design, inasmuch as it is possible to determine the operating characteristics which a given selecting circuit will possess when connected into the working circuit. The importance of equipping carrier systems with selecting circuits uniform in structure and performance cannot be overemphasized. At the same time, if full economic advantage is to be realized from carrier operation, it is equally important that the manufacturing costs to produce the selecting equipment should be consistent with those for the other related equipment.

As may be noted under the discussion regarding performance, it has been possible to develop for this system relatively inexpensive shaping networks and receiving selecting circuits (patent applied for) that meet especially well all transmission requirements imposed. This is accomplished primarily by designing the selecting units for the entire system so that only one type of inductance coil is used throughout; obviously this greatly simplifies the manufacturing problem for selecting circuit equipment from the standpoint of electrical and mechanical dimensions. Advantage is taken of the desirable properties of the air core inductance coil for eliminating the possibility of modulation effects from the selecting circuits. A double tuned circuit is embodied in the shaping networks used at the transmitting terminals. Mounting arrangements for the circuit elements have been worked out in a convenient assembly, as shown in Fig. 4. As may be noted one inductance element is movable with respect to the other fixed inductance element; a calibrated scale is provided in order that any desired degree of coupling may be easily obtained. The major portion of each capacitive element is composed of fixed units, with the remainder made up of small adjustable units permitting closer tuning adjustment after the entire unit has been assembled.

## RECEIVING TERMINAL

Adequate selectivity for separating out the various modulated carrier frequencies at the receiving terminal is obtained from triple tuned circuits embodying the same principles of design and equipment assembly as the transmitting shaping networks. A level-control network is inserted between the 2 halves of the selecting unit, as a convenient means of adjusting the individual channel frequencies to the proper operating level without appreciably affecting the transmission characteristic of the selecting units. A 10-db range for transmission level adjustments is provided in a continuously variable section of the level-control unit. This permits close regulation for optimum operating conditions. Fixed pads may be added to this 10-db unit, if desired. The last tuning condenser of the second section of the selecting circuit is connected in parallel with the input to the receiving channel amplifier, as an efficient means of coupling. Fig. 3 shows in schematic form the entire receiving circuit.

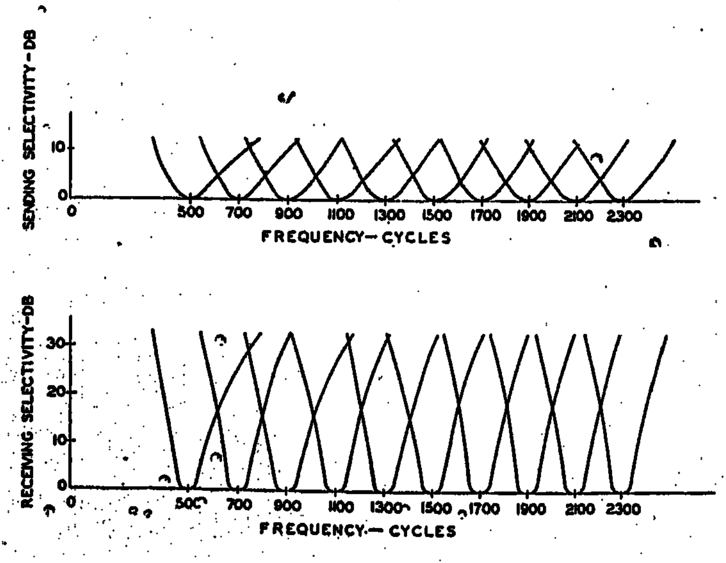

Fig. 6. (Left) Representative transmission characteristics of shaping net-works and receiving selecting circuits

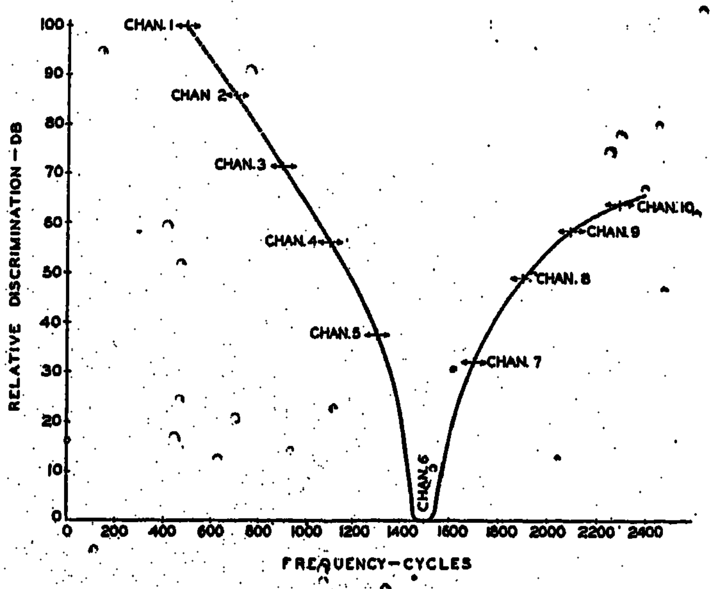

Fig. 7. (Right) Discrimination of a typical receiving selecting circuit

A vacuum tube amplifier having 2 stages of transformer coupled amplification is provided for each individual receiving channel. A maximum over-all receiving circuit sensitivity equivalent to 2.0 milliamperes down 26 to 30 db may be obtained for any of the channels. Vacuum tubes developed for these amplifiers as well as for the repeater amplifiers, have a voltage amplification factor of approximately 6 and an output impedance of 4,000 to 6,000 ohms. They require 0.45 amp filament current at 5 volts and are operated at a plate potential of 150 volts.

Conversion of the received a-c signals to d-c impulses is accomplished by means of a dry copper oxid rectifier. This rectifier is used in series arrangement between the output of the receiving amplifier and the receiving relay. Adapting this type of rectifier to conform to the requirements imposed on the receiving circuit has furnished a stable detector circuit not influenced by power supply variations. Maintenance and operating requirements for this form of detector are negligible.

For the receiving relay a sensitive, multi-winding, polarized telegraph receiving relay is used which requires a current of only a few milliamperes in the operating windings. Two other windings are connected to a local accelerating circuit in accordance with the well-known Gulstad (see "Vibrating Cable Relay," K. Gulstad, *Elec. Rev.*, London, v. 42, 1898; v. 51, 1902) vibrating relay circuit. This tends to insure positive action of the sensitive receiving relay. Furthermore the Gulstad circuit, due to its adjustable vibratory nature, is especially suited for printer telegraph operation. Still another set of windings is used to bias the relay electrically.

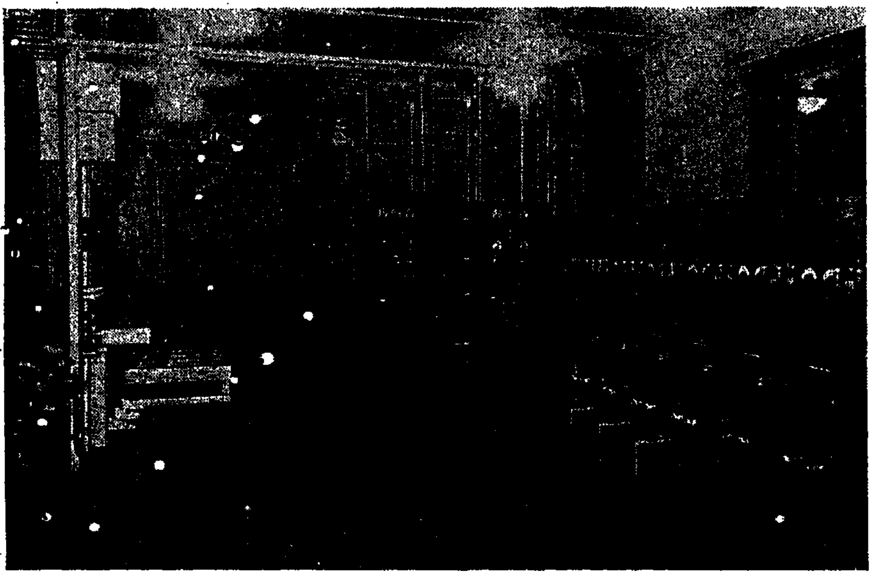

**Fig. 8. New York terminal layout of New York-Washington carrier telegraph system**

Carrier bays for 6 of the 10 channels may be seen at the right

SYSTEM PERFORMANCE

In view of the existing printer plant associated with carrier facilities, a band width capable of handling a 30-cycle dotting speed is all that is necessary to meet present requirements. With the channel bands adjusted for this type of service, it is possible to handle 2-channel multiplex, start-stop, or manual signals commercially. Maximum commercial traffic capability of a 10-channel system operating 4-wire on a 30-cycle basis and working a 2-channel multiplex on each carrier channel as well as on the 4 physical wires, is 3,360 words per min.; 2,400 words of this total is over the carrier. Naturally, a record communication network embodying 2 different types of printer service, along with hand speed telegraph service, thereby is limited in the number of cases where the maximum word capacity of a carrier system can be utilized. For the application at hand, it was more important to standardize the use of carrier channels capable of handling any combination of existing telegraph service used in the present plant.

For the present, carrier systems are operated over existing No. 9 AWG (114.4 mil) copper line wires. This system, even when comprising a complete complement of 10 channels will span distances from 50 to 510 miles (80.5 to 820.6 km) economically and effectively without repeaters. When repeaters are required, they may be spaced up to 275 miles (442.5 km) apart. Each amplifier of a 4-wire repeater has a maximum gain of 28 db and is capable of handling the combined outputs of all channels. Satisfactory operation over a 10-channel system has been demonstrated experimentally over artificial lines through as many as 8 repeaters in tandem, equivalent to a New York-San Francisco system.

As has been stated previously, the inherent operating characteristics of all channels are uniform. An oscillogram showing over-all telegraph transmission over a typical carrier channel is shown in Fig. 5. The telegraph signal transmitted consisted of 30-cycle reversals. The quality of the telegraph transmission may be observed by noting the freedom from bias on comparing traces A and C.

Characteristics of the transmitting shaping networks and of the receiving selecting circuits are shown in Fig. 6. Transmission curves of the receiving selecting circuits arbitrarily show relative discrimination against only the adjacent channel bands. However, the attenuation of the coupled tuned circuit type of selecting circuit employed inherently increases for departures further and further away from the resonant frequency. In order to show this more clearly a characteristic curve of a 1,500-cycle channel receiving selecting circuit is given in Fig. 7; this is typical of the other selecting circuits covering the entire frequency allocation on either side.

Inherent transmission characteristics of the overall channels are suited particularly well to printer operation. Transmission changes as great as ±6 db in the over-all channel equivalent, caused by power or line equivalent variations, will not upset the operation of the printers when initially lined up to operate in the center of the printer range. Printer ranges over the carrier channels are nearly as good as the local ranges attainable on short-circuit.

CONCLUSIONS

Performance data show that the particular carrier telegraph system described fulfils to a practical extent the general requirements set down earlier in this article as an ideal to be approached. This should be evident when it is considered that:

1. Each carrier channel is capable of handling commercially 2-channel multiplex signals at 60 words per multiplex channel, for which speed the apparatus was initially adjusted. Only relatively simple adjustments are required to accommodate signalling speeds suitable for 3- or 4-channel multiplex operation if desired.
2. On the New York-Washington system standard 2-channel multiplex equipment has been operated at the 60-word rate on all of the 10-carrier channels without discrimination.
3. Stability of the carrier system may be judged by the lack of service interruptions over extended periods of time with a simultaneous load of 9 2-way 2-channel multiplex circuits and 1 2-way teleprinter circuit.
4. Channel equipment has been designed to provide economically a large degree of flexibility. It is possible not only to interchange equipment but, at the same time, to secure uniform telegraph transmission at all channel frequencies. These advantages are due mainly to the adjustable features incorporated in the single unit design of the shaping networks and selecting circuits.
5. The introduction of this carrier system into the telegraph plant has not imposed any additional restrictions on the inside or outside plant facilities. An example of this is the retention of the d-c 2-channel multiplex operation, with ground return, over the same wires upon which the carrier system is superimposed.

# Direct Solution of Coupled Tuned Circuits

**A method has been developed for computing easily and accurately the transmission characteristics of a coupled tuned circuit under practical operating conditions. While especially applicable to communication circuits, the method is said to be applicable to all circuits of this general type.**

By
**L. A. KELLEY***
ASSOCIATE A.I.E.E.

Burkholder and Kelley, communication engineers, New York and Toronto

COMMON PRACTISE today for determining the transmission properties of a selecting circuit is first to assume the circuit to be terminated in an infinite number of recurrent identical selecting circuits and then to treat it much as if it were a portion of an infinitely long line having smoothly distributed constants. Such a method has the advantage of requiring less labor than ordinarily would be involved in applying Kirchoff's laws to the circuit in place, but the assumption often leads to large errors and requires the application of several correction factors for each individual point of the transmission characteristic. The labor can be reduced substantially, however, without resorting to this assumption; the manner in which it can be done is the subject of this article. Only recurrent coupled tuned circuits employing magnetic and capacitive coupling will be treated in detail.

## General Theory

The general theory will be limited to repeated identical networks operating between arbitrary terminations. Also, for convenience, the networks will be assumed to be symmetrical and composed of linear impedances, and the terminations equal to each other.

Referring to Fig. 1, let $Z = Z_X + Z_M$, first of all suppose the terminals 1–2 to be connected by short wires to 3–4. Call the current which flows $I_0$; then $I_0 = E/2Z_T$. The current $I_0$ is therefore the current which flows in the output circuit when no circuit entailing a loss is interposed. The attenuation ratio will be expressed as $I_0/I$ where $I$ is the output current flowing under any conditions for the same value of $E$. Furthermore, let $a_n$ represent this ratio where the subscript $n$ indicates the number of symmetrical networks interposed in any particular case; $a_0 = 1$ may be written immediately. Proceeding,

$$a_1 = \frac{E/2Z_T}{\dfrac{E \cdot Z_M}{(Z_T + Z)^2 - Z_M^2}} = \frac{(Z_T + Z)^2 - Z_M^2}{2\,Z_T\,Z_M}$$

Put $a_1 = A$ for the time being; by proper arrangement, then,

$$a_2 = \left[\frac{2Z}{Z_M}(A) - 1\right] \text{ or } (BA - 1) \text{ where } B = \frac{2Z}{Z_M} \text{ and}$$

likewise $a_3 = [B(BA - 1) - A]$ and so on. In general, it may be proved that

$$a_0 = 1$$
$$a_1 = A$$
$$a_2 = BA - 1 = Ba_1 - a_0$$
$$a_3 = B(BA - 1) - A = Ba_2 - a_1$$

and

$$a_n = Ba_{n-1} - a_{n-2} = Ba_{n+1} - a_{n+2} \qquad (1)$$

Equation 1 is perfectly general for the case assumed and is an exact solution. It is the fundamental equation upon which the present method is based. It remains only to express $A$ and $B$ in simple terms for any particular case to establish the ease and utility of the method. This will be

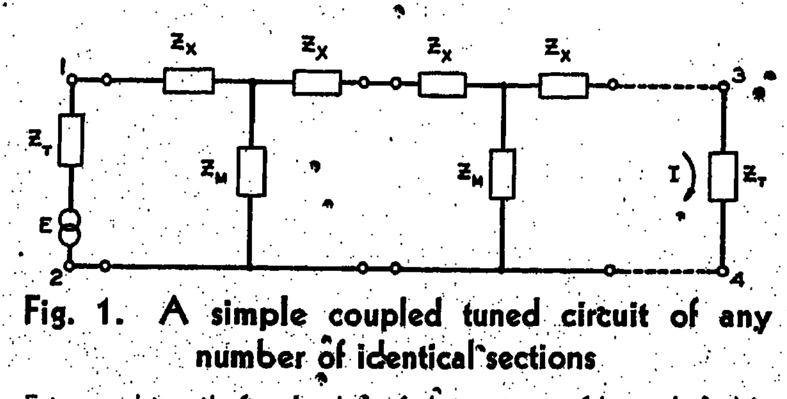

**Fig. 1. A simple coupled tuned circuit of any number of identical sections**

E is an arbitrarily fixed value of alternating emf but adjustable as to frequency; $Z_T$ and $Z_T$ are equal terminal impedances; and $Z_X$ $Z_X$ and $Z_M$ included between 2 pairs of terminals compose each symmetrical network section

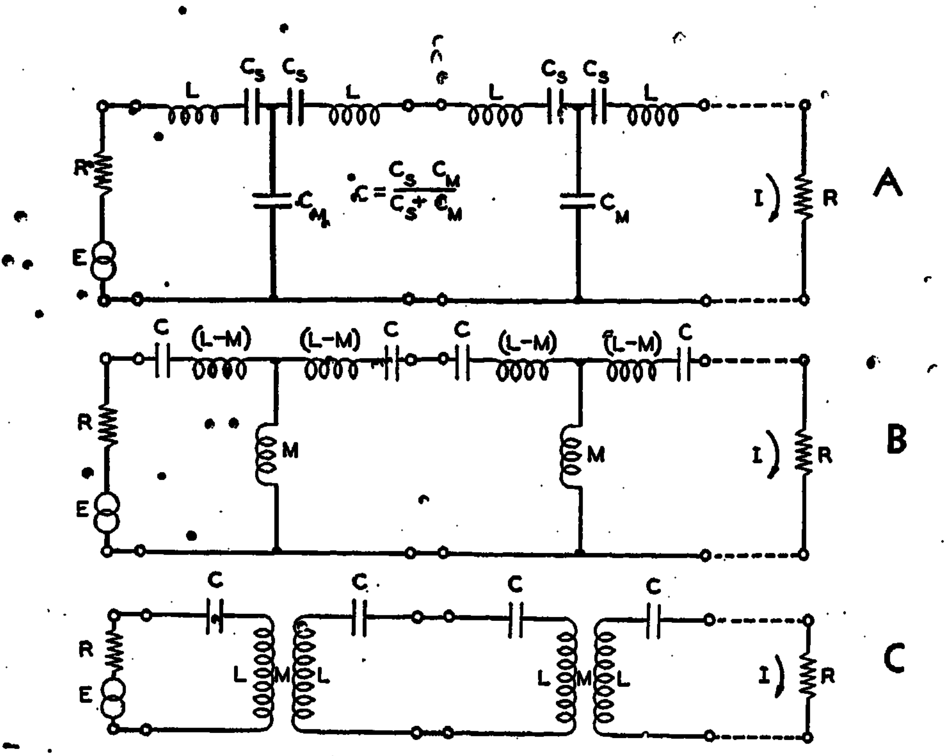

Fig. 2. Typical coupled tuned circuits

done using the well known coupled tuned circuits for illustration.

THEORY APPLIED TO COUPLED TUNED CIRCUITS

A capacitively coupled tuned circuit terminated in equal resistances $R$ is represented in Fig. 2A. Fig. 2B and its equivalent 2C represent magnetically coupled tuned circuits likewise terminated in equal resistances $R$. For the time being $L$ and $C$ will be considered as pure reactances.

In what follows let

$f$ = any frequency

$f_0 = \frac{1}{2\pi\sqrt{LC}}$, the frequency of series resonance

$\omega = 2\pi f$

$K = \frac{M}{L}$ and $\frac{C}{C_M}$, the coefficient of coupling

$b = \frac{f}{f_0}$ with capacitive coupling and

$b = \frac{f_0}{f}$ with magnetic coupling

$R = 2\pi f_0 M$ and $\frac{1}{2\pi f_0 C_M}$ for magnetic and capacitive coupling, respectively.

First consider the case of capacitive coupling as shown in Fig. 2A. Then

$$A = \frac{\left[R + j\left(\omega L - \frac{1}{\omega C}\right)\right]^2 + \left(\frac{1}{\omega C_M}\right)^2}{-j2R \cdot \frac{1}{\omega C_M}}$$

Note that

$\left(\omega L - \frac{1}{\omega C}\right)$ may be transformed to $\frac{1}{\omega C}\left(b^2 - 1\right)$

so that

$$A = -\frac{(b^2 - 1)}{K} + j\left[\frac{b}{2} + \frac{1}{2b} - \frac{1}{2b}\left(\frac{b^2 - 1}{K}\right)^2\right] \tag{2a}$$

and

$$B = j\frac{\left[2\left(\omega L - \frac{1}{\omega C}\right)\right]}{-j\frac{1}{\omega C_M}} = -2\left(\frac{b^2 - 1}{K}\right) \tag{3a}$$

$\left(\omega L - \frac{1}{\omega C}\right)$ may be transformed to $-\omega L(b^2 - 1)$ so that when the coupling is magnetic,

$$A = -\left(\frac{b^2 - 1}{K}\right) - j\left[\frac{b}{2} + \frac{1}{2b} - \frac{1}{2b}\left(\frac{b^2 - 1}{K}\right)^2\right] \tag{2b}$$

and

$$B = -2\left(\frac{b^2 - 1}{K}\right) \tag{3b}$$

There are a number of interesting things to observe about eqs 2a, 3a, 2b, and 3b. In the first place, nothing more is involved that the frequency ratio $b$ and the coefficient of coupling $K$. This simple form is achieved without approximations. For a given value of $K$ these equations show that the attenuation-frequency and phase shift-frequency characteristics are the same in magnitude for all values of capacity and inductance having these configurations, providing the frequency is expressed in terms of the frequency ratio $b$. For given values of $K$ and $b$ the phase shift for magnetic coupling is opposite to that for capacitive coupling. $K$ by definition may have values from 0 to 1. In Fig. 3 are shown a family of curves for $a_1 = A$, or one coupling element with the frequency ratio $b$ and attenuation loss in db as coordinates for several values of $K$. Corresponding phase shift curves are shown in Fig. 4.

It may be seen that the high or low pass selecting circuit is the special case of $K = 1$ for the magnetically or capacitively coupled circuit, respectively. The locus of critical frequency ratio also is shown. These frequency ratios are those at which the steepness of the attenuation frequency ratio curve generally passes through a maximum resulting in low attenuation decreasing rapidly to zero in one direction and increasing rapidly to higher values of attenuation in the other. Quantitatively these frequency ratios are given by setting $(b^2-1)/K = \pm 1$ since the expression occurs as a square in the case of $a_1 = A$ and in still higher powers as $n$ is assigned higher values in $a_n = Ba_{n-1} - a_{n-2}$.

In other words $(b^2-1)/K$ becomes very small quickly when given absolute values less than 1 and increases quickly when given values greater than 1. Therefore $b_1, b_2 = \sqrt{1 \pm K}$ determines the critical frequency ratios which are those between which the structure transmits with little or no attenuation to the comparative exclusion of the range beyond. Similar families of curves could be shown for additional circuit sections and they would reveal a comparatively greater exclusion at the frequency ratios beyond the critical.

By substituting values of $A$ and $B$ found in eqs 2a, 3a, 2b, and 3b in eq 1, the magnitude and phase angle (with respect to the impressed $E$) of the attenuation ratio can be computed exactly and readily for values of $b$, $K$, and $n$. To reduce the labor still more a nomographic chart (Fig. 5) has been prepared to compute the values of the expression $b^2-1/K$ which occurs quite frequently in the formulas for the attenuation ratios.

$$\text{Let } p = \frac{b^2 - 1}{K} \tag{4}$$

Substituting in eqs 2a and 3a

$$A = -p + j\frac{1}{2}\left[b + \frac{1}{b}(1 - p^2)\right] \tag{5a}$$

and

$$B = -2p \tag{6a}$$

Substituting in eqs 2b and 3b

$$A = -p - j\frac{1}{2}\left[b + \frac{1}{b}(1 - p^2)\right] \tag{5b}$$

and

$$B = -2p \tag{6b}$$

The chart in Fig. 5 may be used to solve eq 4 since a straight line connecting $b$ and $K$ will cut the $p$ scale in a value which satisfies the equation.

Transmission characteristics for structures having more than one reactance network interposed may be computed by substituting in eq 1; for example

$$a_0 = 1$$

$$\left.\begin{aligned} a_1 &= -p \pm j\frac{1}{2}\left[b + \frac{1}{b}(1 - p^2)\right] \\ a_2 &= -2p(a_1) - a_0 \\ a_3 &= -2p(a_2) - a_1 \\ &\text{etc., where } A = a_1 \text{ and } B = -2p \end{aligned}\right\} \tag{7}$$

The upper part of the double sign applies to capacity coupling; the lower, to magnetic coupling. Values of $a_n$ in general will be of complex form or $a_n = \bar{a}_n/\underline{\varphi_n}$; $\varphi_n$ will be the phase shift with reference to the impressed emf and $\bar{a}_n$ may be expressed in decibels, $a_n$ (db) $= 20 \log_{10}\bar{a}_n$.

So far the structure has been assumed to be terminated in resistances $R$ such that

$$R = 2\pi f_0 M \text{ or } \frac{1}{2\pi f_0 C_M}$$

This corresponds to the condition of maximum energy transfer at resonant frequency $f_0$ and should be found satisfactory in most cases. For some reason one might wish to consider other values of $R$. The present method can be extended quite easily to cover such cases. Call the new value $R'$ and represent it as a function of $R$ such that $R' = hR$. Now

$$\left.\begin{aligned} a'_0 &= 1 \\ a'_1 &= -p \pm j\frac{1}{2}\left[bh + \frac{1}{bh}(1 - p^2)\right] \\ a'_2 &= -2p(a'_1) - a'_0 \\ a'_3 &= -2p(a'_2) - a'_1 \\ &\text{etc., where } A = a'_1 \text{ and } B = -2p \end{aligned}\right\} \tag{8}$$

A set of curves is shown in Fig. 6 illustrating the effect of giving different values to $h$ when $K = 1$. The importance of the termination in its effect on the resulting characteristic is well shown by comparing the curves for $h = 2$ and $h = 1/2$ with the one for $h = 1$. A curve for $h = \sqrt{2}$ which corresponds to a termination of $R = \sqrt{2L/C}$ is shown also to indicate the possibilities of choosing the termination to bring out a desirable shape for the transmission characteristic.

Heretofore, the coils and condensers have been considered as pure reactances; while for certain purposes it may be safe to assume this, of course it is not possible to build them without some resistance. Make this a function of $R$ so that the resistance of one complete mesh is $r = 2dR$. Accordingly

$$\left.\begin{aligned} a''_0 &= 1 \\ a''_1 &= -p(1 + d) \pm j\frac{1}{2}\left[b(1 + d)^2 + \frac{1}{b}(1 - p^2)\right] \\ a''_2 &= -2(p + jbd)a''_1 - a''_0 \\ a''_3 &= -2(p + jbd)a''_2 - a''_1 \\ &\text{etc., where } A = a''_1 \text{ and } B = -2(p + jbd) \end{aligned}\right\} \tag{9}$$

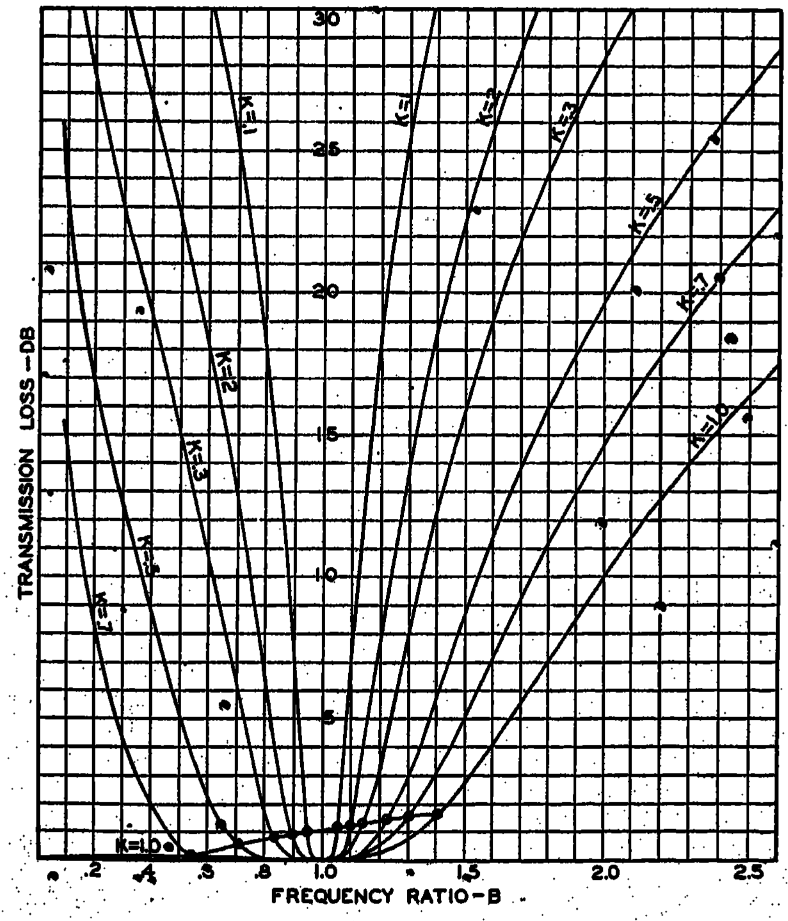

**Fig. 3.** (Left) Attenuation-frequency ratio curves for a tuned circuit having one coupling unit

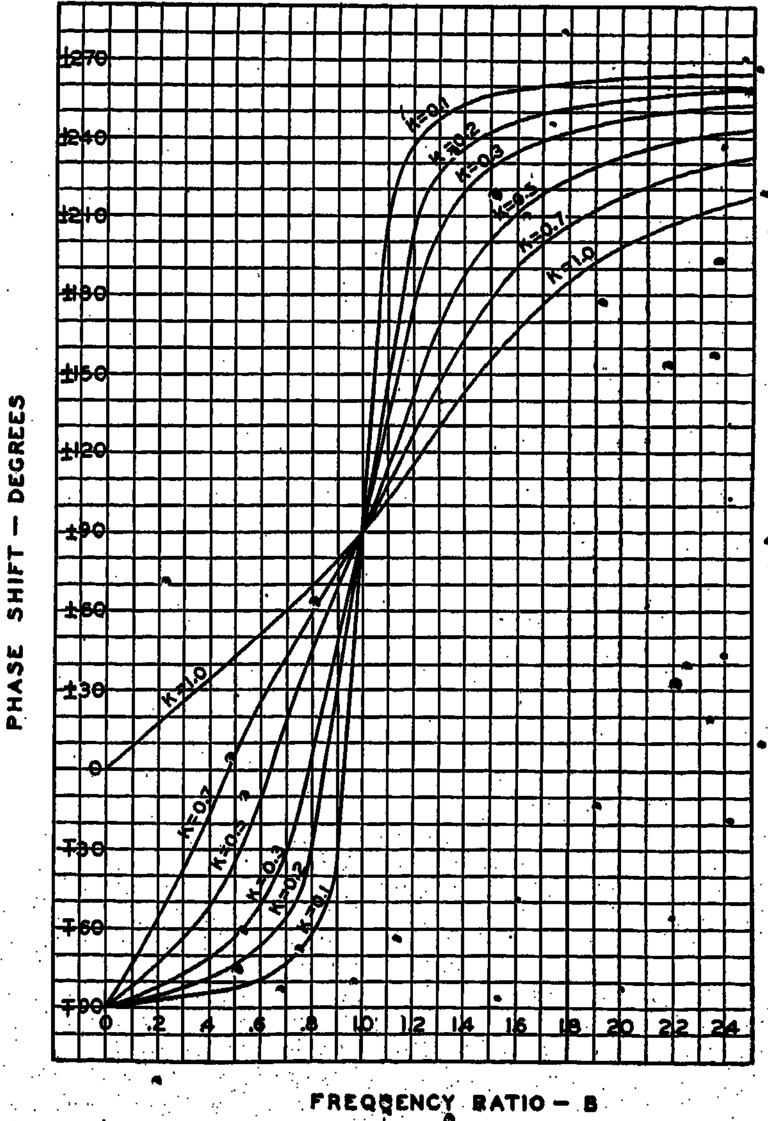

**Fig. 4.** (Right) Phase shift-frequency ratio curves for a tuned circuit having one coupling unit. Use upper sign for capacitive, lower sign for magnetic coupling

The effect of both dissipation and changed termination is given by

$$\left.\begin{aligned}
a'''_0 &= 1\\
a_1''' &= -p(1+d) \pm j\frac{1}{2}\left[bh(1+d)^2 + \frac{1}{bh}(1-p^2)\right]\\
a_2''' &= -2(p+jbd)a_1'' - a_0'''\\
a_3''' &= -2(p+jbd)a_2'' - a_1'''\\
&\text{etc., where } A = a_1''' \text{ and } B = -2(p+jbd)
\end{aligned}\right\} \qquad (10)$$

The foregoing formulas are summarized in Table I.

## DESIGN OF COUPLED TUNED CIRCUITS

The formulas just obtained immediately will suggest methods for designing actual structures for any practical case for they enable the transmission characteristics of this important class of selecting circuits to be readily investigated. To cite an example it will be assumed capacitively coupled tuned circuits are to be used. Data that might be required are, circuit impedances between which the structure will be inserted, the frequency limits between which it is desired to transmit freely, and the attenuation which must be exceeded for certain frequencies outside of the transmitting range.

Call the critical frequencies $f_1$ and $f_2$. Remembering that

$$\frac{b_1}{b_2} = \frac{f_1/f_0}{f_2/f_0} = \frac{\sqrt{1-K}}{\sqrt{1+K}}$$

the value of $K$ and also $f_0$ may be calculated. Suppose the circuit impedances to be equal and represented by $R$. Then the coupling capacity $C_M$ (Fig. 2A) will be found by $C_M = 1/(2\pi f_0 R)$. The value of $C$ will be $C = KC_M$, $C_S = (C \cdot C_M)/(C_M - C)$, and $L = 1/[(2\pi f_0)^2 C]$.

In general the condenser resistance may be neglected and reasonable values of effective resistance of the coils $L$ over the frequency range of interest may be estimated from an abundance of data. Then using the second line of Table I the values of $A$ and $B$ can be computed from which the number of sections required to attain sufficient attenuation outside the transmitting range may be easily determined. Slight adjustments of the band width can be made readily by changes in K and proportional changes in the frequency scale without making a completely new series of computations. The structure then can be assembled with the assurance that the transmission characteristics thus computed will agree closely with measured results.

If the impedances between which the structure is to be inserted are unequal, the inequality may be taken care of by means of a transformer having a suitable impedance ratio or by stepping the circuit impedance up or down in one or more successive meshes remembering that $Z_M = \sqrt{R_1 R_2}$ where $R_1$ and $R_2$ are the circuit impedances of the successive meshes at $f_0$. The condenser and inductance reactance values will be proportional to $R_1$ and $R_2$ in their respective meshes, but the transmission characteristics will remain unchanged so long as the ratio

of reactance to resistance of the different size coils is the same.

## APPROXIMATIONS

Ordinarily, where many circuits of this kind are to be designed it would be convenient to have families of curves plotted covering the range of variables most often desired and interpolate for particular values. It might be desirable, however, to make a rough curve using approximating methods. Many ways suggest themselves but a few which may be helpful will be indicated. The loss in transmitting range, for example, may be gaged from the loss at the frequency $f_0$ which in the case of no dissipation is zero db. Where there is dissipation, it is very closely equal to 20 $\log_{10}[(2R + \Sigma r)/2R]$ db since $r$ is nearly always small compared with $R$. In the attenuation range $r$ usually can be neglected. Moreover, if the attenuation is appreciable (say 10 db or more) for one section, the attenuation for additional sections will be given by adding for each additional section 20 $\log_{10}(2p)$ db to the db attenuation of one section.

It is interesting to consider the case of radio frequency tuned circuits where the fractional change in frequency over the range of interest is extremely small even though it involves traversing a comparatively large number of absolute cycles per sec. Referring to eqs 2a and 2b

$$a_1 = -\left[\frac{b^2-1}{K}\right] \pm j\left[\frac{b}{2} + \frac{1}{2b} + \frac{1}{2b}\left(\frac{b^2-1}{K}\right)^2\right]$$

Assume that $b = 1 \pm \Delta b$ and that $\Delta b$ is very small compared with unity. Whence

$$\left(\frac{b}{2} + \frac{1}{2b}\right) = 1 \text{ approximately}$$

$$(b^2 - 1) = \pm 2\Delta b = \pm\frac{2\Delta f}{f_0} \text{ approximately}$$

Substituting

$$a_1 = -\frac{\pm 2\Delta f}{f_0 K} \pm j\left[1 - \frac{1}{2}\left(\frac{\pm 2\Delta f}{f_0 K}\right)^2\right]$$

or in absolute magnitude

$$\bar{a}_1 = \sqrt{1 + \frac{1}{4}\left(\frac{\pm 2\Delta f}{f_0 K}\right)^4} \text{ approximately}$$

The limiting frequencies of free transmission are derived as before by letting $\pm 2\Delta f/f_0K = 1$. The band width is then $W = f_0K$. Let $f_0K = 1$ in the approximate equation and plot $\bar{a}_1$ in decibels against frequency departure $\Delta f$. Such a curve is shown in Fig. 7 for one coupling unit, but since it is symmetrical about $\Delta f = 0$ only half is drawn. To use the curve look up the attenuation corresponding to $\Delta f$ and then multiply the value of $\Delta f$ by the band width $W$ which gives the actual departure in cycles per second from $f_0$ having that attenuation.

As a specific example, suppose it is desired to investigate the selectivity curve for a coupled tuned circuit with one coupling element such that it will transmit a band of 5 kc at a resonant frequency of 1,500 kc, i. e., from 1,502.5 kc to 1,497.5 kc. Since $W = f_0K$, $K = 1/300$. Then multiply the abscissas of Fig. 7 by 5 kc and the curve for one coupling unit automatically becomes the selectivity curve with abscissas in kilocycles off resonance. Actual values for the coils and condensers depend upon the circuit impedance and are determined readily in the manner previously shown.

These approximations may be extended to tuned circuits of more than one section. Take 2 sections for example.

$$B = -2\left(\frac{b^2-1}{K}\right) = \frac{2\Delta f}{f_0 K} \text{ approximately}$$

In $a_2 = BA - 1$ substitute the approximate expressions for $A$ and $B$, whence

$$a_2 = \left[2\left(\frac{2\Delta f}{f_0 K}\right)^2 - 1\right] \pm j - 2\left[\frac{2\Delta f}{f_0 K}\right]\left[1 - \frac{1}{2}\left(\frac{2\Delta f}{f_0 K}\right)^2\right]$$

The absolute magnitude

$$\bar{a}_2 = \sqrt{1 + \left(\frac{2\Delta f}{f_0 K}\right)^6}$$

Here again the band width is $W = f_0K$ and a similar selectivity curve is drawn in Fig. 7 for 2 coupling units. This curve may be used in exactly the same manner as indicated for the first curve. The same is true of the curve for 3 coupling units. Indeed, all of the curves are drawn to the same scale of frequency and are directly comparable in regard to their selecting properties. It is possible, therefore, to see at a glance the selectivity to be expected from 1, 2, or 3 sections of either capacitively or magnetically coupled tuned circuits providing $K$ is small enough so that $b$ need depart only slightly from unity to cover the frequency range of interest. It is assumed also that $R = Z_M$ and dissipation is negligible. They do, nevertheless, afford considerable information for a small amount of effort, since there is no special advantage in using a different value of $R$ and dissipation will cause a more or less rounding off at the critical frequencies, an exceedingly small range of frequencies to investigate more precisely. No doubt, other ways of approximating will suggest themselves.

It was noted earlier in the paper that the coupled tuned circuits were to be treated as an example of the general scheme based upon eq 1. For other types of structures the first step would be to convert the expressions for $A$ and $B$ in terms of the structure into the simple form of ratios and proceed along the same line as shown here for coupled tuned circuits.

# Engineering Progress—Help or Hindrance?

**Engineering progress is said to be neither good nor bad; it may help man or hinder him, depending upon how it is used. This is the fourteenth article of the Engineering Foundation's symposium "Has Man Benefited by Engineering Progress?"**

By
S. VAN MIERLO

Dept. head, Laboratoires
De La Societe Le Materiel
Telephinique, Paris

NOT ALL progress is real gain. If we increase our needs at the same rate as we increase our facilities, there is no *real* gain. We have means to travel quickly, but why should we travel quickly? Mainly because modern life needs it; but we have to travel much more and the total delay and discomfort may be greater.

While some diseases are much attenuated, new ones are due to the new way of living. Would it be real progress to find a radical method of curing tuberculosis? Yes, given the present conditions; but are not these conditions the main reason why tuberculosis became so widespread? Surgical methods are much improved, but are most cases not due to our way of living: accidents, lack of exercise, unsuitable food?

What is happiness? If one considers his own life, he will find that the notion "happy" is relative for what makes us relatively happy for a time is not necessarily of real benefit. Real happiness should last, and can be procured only by what is really good; it is practically independent of material conditions—an abandoned, poor, sick man may be happy. Experience tells us that no *material* good has ever given true and lasting satisfaction. Every time we reach such a goal we find that it is not the thing we expected.

Experience of past ages shows that no civilization, no culture, no progress, no improved means of communication, no form of government, in short, no improvement of the outer influences, can bring peace and make man really happy. The great obstacle is man himself. He must change individually. The famous Claude Bernard used to say:

> "Science has made great progress; man's passions remain the same. . . . Science does not change instinct, it reinforces it and increases its strength."

Engineering progress is neither good nor bad in itself. Engineering is concerned principally with the lower class of good. Material conditions have been much improved, particularly for the country people; but we may ask whether these conditions could not have been improved sufficiently in a more efficient way by a change in general organization even without modern progress. For the higher class of good, engineering progress may be a help, but at the same time a hindrance.

## RIGHT USE OF ENGINEERING PROGRESS

Engineering progress and scientific discoveries show us more clearly the marvels of creation and should lead us logically to the invisible and absolute things. Many men through whom this progress was made possible could say with Faraday:

> "Yet even in earthly matters I believe that the invisible things of Him from the creation of the world are clearly seen, being understood by the things that are made, even His eternal power of Godhead; and I have never seen anything incompatible between those things of man which can be known by the spirit of man which is within him and those higher things concerning his future, which he cannot know by that spirit."

Engineering progress helps to manifest man to himself. A child shows his childliness by choosing his sort of good; a man can likewise recognize his mental or spiritual position by what he considers as good. The way to real progress is understanding and acknowledgment of one's real position. If experience (and engineering developments are an important factor) teaches man that he is far from perfect and that his own efforts even by giving marvelous results *in their proper sphere*, cannot lift him above himself, and that he needs make use of a power belonging to a higher sphere, he will make real progress and come to real and lasting happiness.

### WRONG USE OF ENGINEERING PROGRESS

Engineering progress may hinder us from reaching the highest good. In general, modern nervous life gives fewer opportunities to examine calmly the problems of life; it draws all attention to material things. Such progress may in another way have a harmful effect. Man may consider himself as the most superior being. He may consider his achievements in the material sphere as proof of his own capabilities in any sphere of existence. He may expect to come, through culture, science, and arts, to a state of universal peace and real happiness. If he thinks this way and places himself above all, he will pass through bitter experiences; then engineering developments will have been misused. Observation shows that they often are misused; but that is the fault of man, not of engineering progress.

Great progress has been made in material things. However, as many facilities are needed by the new conditions, the final gain is not so large as may be estimated at first sight. Further, any progress in the material sphere can give only some relative and temporary happiness. Absolute and lasting happiness can have its source only outside of the human sphere and in order to attain such a state of happiness, the inner man must be changed. Material progress may help if rightly used, but also may hinder if wrongly used. Pride in his own achievements may blind man to the extent that he does not see his real needs and is kept from looking for real happiness where it can be found.

**Laboratory tests using water as a medium indicate that the vibration of a conductor used for transmitting electric power can be diminished materially by the use of different shapes of cable cross-sections. The investigation shows further that of the various specimens tested, cables having a triangular cross-section show the least tendency to vibrate.**

BECAUSE of the general increase in unit working loads as well as in the sizes of conductors on electric power transmission lines, vibration of these conductors has become a serious problem. Overhead conductor vibration probably was reported first in 1923 as deteriorating the mechanical characteristics of conductors, by some of the power companies of California. These vibrations seldom have an amplitude exceeding 2 in. Node lengths vary considerably and the frequency is of the order of from 10 to 100 cycles per sec.

Numerous mechanisms and appliances have been suggested for overcoming conductor vibrations, and some of these function very well indeed. However, such devices always are subject to the criticism that ultimately they may account for more harm than good. At the same time if the cause of the vibration can be determined, and preventives applied at the source, there will be then but little danger of trouble occurring later at some unexpected point.

Following reports of a field observation from a Pacific Coast power company, to the effect that a 3-strand cable did not vibrate as much as a standard cable,[6] also that a single strand wrapped about a cable seemed to reduce the vibration,[7] it was thought that the problem might be solved by modifying the conductor sections rather than by adding reenforcements or dampers. Studies made later by Thoma[8] confirmed this assumption, and showed that the section of the cable did play an important part in the vibration characteristics. It was thought that by upsetting the symmetry of the conductor section, eddies formed on the lee side of the conductor would be disrupted. This is explained in the following paragraphs.

### THEORY OF NON-SYMMETRICAL SECTIONS

A $^5/_8$-in. diameter round rod with a $^1/_8$-in. diameter wire spiralled about it, as shown in Fig. 1, has been

---

Based upon "Vibration and Fatigue in Electrical Conductors" (No. 32-69) presented at the A.I.E.E. summer convention, Cleveland, Ohio, June 20–24, 1932.

selected to indicate the complicated system of frequencies brought about by the eddy formation at several successive cross-sections along the cable. Balancing of the eddy forces is demonstrated at individual pairs of cross-sections. A $^5/_8$-in. plain round rod is examined also for comparison; as may be seen, there is no balancing action in this type of conductor.

Four variables that modify the resultant eddy action behind the rod and wire are introduced in each individual cross-section, namely: (1) frequency, (2) phase, (3) amplitude, and (4) neutral vibration plane. Each of these is studied in detail as follows:

1. Frequencies were calculated from the Relf and Ower[1] formula.

$$\text{Frequency} = \frac{V}{D} \times \phi\left(\frac{VD}{e}\right)$$

Assuming constant velocity of flow, the frequency is proportional to the diameter of the section; hence varying this diameter varies the frequency. In the case shown in Fig. 1, variation is brought about by spiralling the wire about the rod. The effective diameter of the combination will be the diameter of the rod plus a portion of the diameter of the wire. The diameters only were considered in determining the frequencies; theoretical curves were plotted from these values. These curves then represent, to some scale, the actual frequency of the section.

2. Phase of the vibration of an individual section is governed by the position of the outer wire and has been plotted accordingly in the diagram.

3. Force acting in the direction of vibration is,[5]

$P = KV^2 \times D$ per ft run per lb

where $P$ = force, $V$ = velocity, and $D$ = diameter.

Assuming velocity constant, the force will be proportional to the diameter. The amplitude of the vibration, therefore also will be proportional to the diameter. For each section in the diagram (Fig. 1) the maximum amplitude has been plotted equal to the effective diameter and therefore represents to scale the true amplitude.

4. Vibration will take place about the center of impact of the section; this is offset from the horizontal diameter of the rod, and has been indicated in Fig. 1 by a broken line.

Eddy formation and resulting forces have been plotted for an instantaneous position of the rod and will reverse at periods according to the frequencies involved, as indicated in Fig. 1 by the double arrows for the round rod and by the double wave at cross-section 4. No attempt has been made here to establish the exact mathematical values of the quantities involved, but this is being investigated. The diagram thus illustrates the principle qualitatively, but not quantitatively.

It may be seen that at sections 3 and 7, and at 2 and 6, Fig. 1, the frequencies and amplitudes (therefore forces) are equal but are 180 deg out of phase. They will, therefore, tend to balance one another in the direction of vibration, thus reducing this objectionable feature. In the symmetrical round rod, the eddy formation is identical at each section and no balancing tendency is evident. At section 4 of the combination of rod and wire, an unstable condition is introduced due to the forces on the sections on either side of it tending to move the conductor in opposite vertical directions.

It must be realized that this discussion deals with a small length of cable and with an 8-in. lay of the wire; the 2 boundary sections are separated by 8 in. Similarly, with 3-strand cable the boundary sections would be separated by only $2^2/_3$ in. In practise it is highly probable that over such a small strata in

comparison to the length of the span, wind velocity would be approximately constant.

## Special Sections Available for Study

The single wire spiralled about the rod is impracticable, for on the application of tension the load on the cable becomes eccentric. This analysis, however, points the way to modifying, in a practical way, the fundamentals of vibration in cables. For instance, in a 3-strand cable, this same complication of frequencies would be present, but the tension would be uniformly balanced over the cable section. The 4-strand cable also is a good example and is in common use, more especially in steel wire rope. Almost any sector or acorn shape may be made without much loss of mechanical strength by rolling or hammering the round cable as in 3-phase insulated cables.

As a basis upon which to work, it was decided to make specimens of sections of cables that were statically balanced so that they would not pull eccentrically. The section should, however, be unsymmetrical about the horizontal axis of the cable and at the same time be unsymmetrical for successive sections along the cable; in other words, the section should simulate those characteristics which seemed to interfere with vibration in the wire-wrapped cable. It was evident that as uniform an eddy action could not be expected over a length of these special cables as appears to be the case with standard cables or round rods, with a consequent reduction of the power input from the wind.

## Laboratory Work

Experiments to determine the effect of different cable cross-sections, and the amplitude of vibration, based upon the foregoing assumptions, were carried out in the hydraulic laboratory of the University of Toronto. Experiments and methods used by Doctor Thoma were followed quite closely, water being used as a medium. Specimen conductors of various peculiar shapes were tested at 5 different velocities of water ranging from 4 to 7 in. per sec. The specimen was fastened to a flat steel strap 1 in. by $^1/_{32}$ in. and 5 ft long. This strap was used in preference to the elastic steel rod which Thoma used, as it restricted most effectively any movement in the direction of the flow of water. A light pointer attached to the strap traced the wave motion on a smoke chart attached to the drum of a vibrograph. The specimens were divided into 5 groups, each group having a circular sample as a standard of comparison. Projected dimensions, or effective diameters, of all the specimens within each group were approximately the same, the object being to obtain the same frequencies of vibration. In order that the vibrating system in each group should be as nearly as possible the same, the specimens were made equal in weight and with centers of mass at the same point as that of the standard.

Adjustment for resonance was brought about by varying the length of the strap between the specimen and the clamp until the maximum amplitude of vibration of the strap was obtained. Other sections in the corresponding group were treated similarly. That the required similarity was obtained was evidenced by the fact that in each group adjustment for fundamental resonance of the various samples was negligible and was seldom necessary at all so that the natural frequencies of the systems were approximately identical.

Owing to variations in the speed of the smoke chart, no exact check of the observed frequencies could be made, but the fact that no important adjustments were required within the groups indicates that approximately identical frequencies were obtained in each case. In any case, the final purpose of the experiments was to derive qualitative rather than quantitative results. The design of specimens giving the same vibrating systems within each group (i. e., having the same mechanical impedance) permitted the use of vibration amplitude as a measure of the relative damping.

## CONCLUSIONS FROM HYDRAULIC EXPERIMENTS

Qualitatively the following conclusions may be drawn from the experiments just outlined, pending more practical experiments using air as a medium:

1. As evidenced by the charts shown in Fig. 2, it may be seen that so far as hydraulic experiments are concerned, the twisted triangular section most satisfactorily overcomes the tendency to vibrate.

2. It can be noticed also that practically all the sections tested decreased the amplitude by at least 50 per cent compared with the round rod (Fig. 3). From the results, it would seem advisable to construct a cable having approximately a triangular cross-section. Fig. 4 shows a series of cable sections derived from the basic sections that in the laboratory evidenced a considerable reduction in tendency to vibrate.

3. If these special triangular and rectangular sections prove impracticable in cables, they still may be used in outdoor buses where difficulties of this nature may arise in the future.

## FUTURE INVESTIGATION WORK

Upon the basis of these tests and the conclusions drawn, the following points are proposed or suggested for future investigation:

1. At present special cables approximating triangular cross-sections have been made and are being strung in air to see how closely the hydraulic experiments simulated practical conditions. Three sections have been suggested: (1) the ordinary 3-strand cable which was casually observed in the West as being comparatively free from vibration; (2) a 9-strand cable made up of 3 strands of 3-strand cable with rope lay; and (3) a special 9-strand cable using 2 sizes of strands, the 3 larger strands so placed in the outside layer as to give approximately the desirable triangular effect (Fig. 5). The special rope lay cable introduces a feature which may be of great importance. Due to a characteristic of the stranding, air-gaps that will not collapse under tension have been introduced. The presence of these air-gaps may serve to upset further the sequence of eddies behind the cable.

2. Acting conjointly with so-called "stiction" and "interstrand friction," the elastic properties of the individual strands of a standard cable will tend to modify the vibration. Investigation should be made with the object of segregating these and to determine the comparative importance of the damping in each case. Does interstrand friction absorb any energy at all at the comparatively long radii of curvature found in conductor vibration phenomena?

3. Experiments should be carried out to verify the following predictions made for 2 cables, (1) 6 x 0.2108, 7 x 0.0705, 266,800 cir mils A.C.S.R. "Owl"; and (2) 30 x 0.1059, 7 x 0.1059, 336,400 cir mils A.C.S.R. "Oriole." An attempt was made to predict mathematically the characteristic dimensions of vibration in these two cables and to balance energy input against energy dissipated, the remainder of the energy doing work on the cable at points of discontinuity, such as clamps. Many assumptions had to be made. Initial attempts at measurements in the field were unsatisfactory and this work was temporarily abandoned.

4. A determination of the actuating force per foot length of cable should be carried out. This could be done in a suitable wind tunnel with adjustable elastic supports for the specimen under test.

## PRACTICAL DIFFICULTIES

There are many objections to any departures from standard cables such as are indicated by these experiments. It is hoped therefore that so far as vibration is concerned the proposed sections will display new properties which in some cases at least will outweigh practical difficulties, such as standardization.

Some of the possible objections to some of the cross-sections proposed are that the electrical losses may be increased to some extent; the increased diameters would account for greater wind pressures and sleet loadings; difficulty would be experienced in making joints. In addition, 2 sizes of strands in 1 cable would be a digression from the standards, and if more than 1 pass through the stranding machine be required on account of these various sizes of strands, the cable cost would be increased.

Discussions and studies of these details are deferred until there is an opportunity to confirm in a practical way that the vibration amplitudes are suppressed in air, as they have been found to be in water.

# Single-Phase Short-Circuit Torque

The analysis of synchronous machines previously published by Doherty and Nickle is expanded in this article to include the calculation of torque due to single-phase short-circuit. The torque is expressed as the sum of odd and even harmonic series which are simply related to those previously derived for the armature current. The effect of amortisseur windings also is taken into account. As an illustration of the application of the equations, the short circuit torque is calculated for a 100,000 kva generator.

By

**M. L. HENDERSON**
ASSOCIATE A.I.E.E.
General Elec. Co., Schenectady, N. Y.

EXPRESSIONS for the single-phase short-circuit torque of a synchronous machine may be derived from previously published equations for 3-phase short-circuit torque and for single-phase short-circuit currents. These previously published equations are given in a series of articles by R. E. Doherty and C. A. Nickle (namely, SYNCHRONOUS MACHINES—I AND II, A.I.E.E. TRANS., v. 45, 1926, p. 912–42; SYNCHRONOUS MACHINES—III, A.I.E.E. TRANS., v. 46, 1927, p. 1–18; SYNCHRONOUS MACHINES—IV, A.I.E.E. TRANS., v. 47, 1928, p. 457–92; SYNCHRONOUS MACHINES—V, A.I.E.E. TRANS., v. 49, 1930, p. 700–14) particularly on "Synchronous Machines—IV" which gives expressions for the currents resulting from single phase short circuits.

As the present article is based on the theory and equations developed in "Synchronous Machines—IV," the simplifying assumptions made therein are necessarily used here. The most important of these assumptions are that:

1. Saturation is negligible.
2. The open circuit voltage is sinusoidal.
3. Armature and field resistances are negligible except in determining decrements.
4. The short circuit occurs at no load.
5. Synchronous speed is maintained during short circuit.

Throughout the article all quantities are expressed in the per unit system unless otherwise noted; and instantaneous values of voltage, current, mmf, flux linkages, and torque are used.

## GENERAL PROCEDURE

The synchronous machine is considered as having a main field winding in the direct axis and amortisseur windings in both the direct and quadrature axes, thus introducing both subtransient and transient reactances. The general procedure employed in "Synchronous Machines—IV" is used to determine armature current and rotor excitation, except that 3-phase line-to-neutral reactances are used in place of single phase static reactances.

The values of the armature current and mmf, before the effect of the decrements is appreciable, are determined by the open circuit armature voltage, $e_o$, the position of the rotor when short circuit occurs, and the subtransient reactances. The armature mmf is resolved into components over the direct and quadrature axes and is expressed in terms of odd and even harmonic series. The fundamental of the odd series current induces a transient direct current in the direct axis rotor circuits; all other harmonic components induce alternating currents in the rotor windings. Consequently, on short circuit the d-c rotor excitation is increased from the value existing just before short circuit to a new value which includes a component induced in the 2 direct axis rotor windings by the armature current. The decay of the induced d-c components of excitation and that of the odd series component of the armature current are determined by the decrement factors of the rotor windings in the direct axis.

It is assumed that the decay of the unsupported rotor excitation may be represented with sufficient accuracy by 2 decrement factors, one applying to the decay of induced direct currents in the amortisseur winding, and the other applying to the decay of that part of the d-c component of field current which the exciter does not maintain. The "rotor linkage factor," $F$, represents the total rotor linkages at any time after short circuit, as a fraction of the rotor linkage just before short circuit. The following equation gives $F$ as a function of time, in terms of machine constants:

$$F = \frac{x_d'' + x_2}{x_d + x_2} + \frac{(x_d'' + x_2)\,(x_d - x_d')}{(x_d + x_2)\,(x_d' + x_2)}\,\epsilon^{-\sigma_f' t} + \frac{x_d' - x_d''}{x_d' + x_2}\,\epsilon^{-\sigma_f'' t} \qquad (1)$$

where

$x_d$ = direct axis synchronous reactance
$x_d'$ = direct axis transient reactance
$x_d''$ = direct axis subtransient reactance
$x_q''$ = quadrature axis subtransient reactance
$x_2$ = negative sequence reactance = $\sqrt{x_d'' x_q''}$
$\sigma_f'$ = the decrement for the unsupported linkages in the main field, with the armature short-circuited single-phase $\doteq \dfrac{x_d + x_2}{x_d' + x_2}\sigma_o'$
$\sigma_o'$ = the decrement for unsupported field linkages with the armature open circuited
$\sigma_f''$ = the decrement for induced direct currents in the amortisseur on single phase short circuit $= \dfrac{x_d''\,(x_d' + x_2)}{x_d'\,(x_d'' + x_2)}\sigma_a''$

---

Based upon "Single-Phase Short-Circuit Torque of a Synchronous Machine" (32-72) presented at the A.I.E.E. summer convention, Cleveland, Ohio, June 20–24, 1932.

$\sigma_s''$ = the amortisseur winding decrement for 3-phase short-circuit at the machine terminals
(Since in the per unit system time is measured, not in seconds, but in electrical radians traversed at the normal frequency, $f$, the decrements above are $1/(2\pi f)$ times the reciprocals of the respective time constants in seconds.)

The linkages in the short circuited armature winding are maintained, at the instant just after short circuit, by the induced d-c component of armature current. These linkages must decay with the d-c component of armature current. For convenience, an "armature linkage factor," $A$, is introduced. It represents the linkages of the short circuited armature winding at any time after short circuit as a fraction of the maximum linkages of that winding before short circuit. As shown in "Synchronous Machines—IV," the even series components of armature current and the odd series components of rotor excitation are proportional to the d-c component in the armature, so that their decay is also represented by the armature linkage factor, $A$.

The expression for this factor is

$$A = \epsilon^{-\sigma_a t}\cos\alpha \tag{2}$$

where

$$\sigma_a = \frac{3(k^2+1)}{4k^2}\,\frac{r}{x_2}$$

$k$ = 1, for line-to-neutral short circuit
$k$ = $\sqrt{3}$, for line-to-line short circuit
$r$ = the per unit armature resistance, line-to-neutral
$\alpha$ = angular position of the direct axis at the instant of short circuit, measured in the direction of rotation from the axis of the armature winding.

Inserting the armature and field linkage factors $A$ and $F$, respectively, in equations which are given in "Synchronous Machines—IV," the armature current at any time after single phase short circuit may be expressed in finite trigonometric form, as follows:

$$i = \left(\frac{3}{2k}\right)\frac{2e_o[F\cos(t+\alpha) - A]}{H} \tag{3}$$

where

$e_o$ = armature voltage before short circuit
$H = (x_d'' + x_q'') + (x_d'' - x_q'')\cos 2(t+\alpha)$

The equivalent Fourier series expansion is:

$$i = \frac{3}{2k}\left[\frac{2e_oF}{x_d''+x_2}\mathrm{O} - \frac{e_oA}{x_2}\mathrm{E}\right] \tag{4}$$

where

$$\mathrm{O} = \text{odd series} = \frac{(x_d''+x_2)\cos(t+\alpha)}{H}$$
$$= \cos(t+\alpha) + b\cos 3(t+\alpha) + b^2\cos 5(t+\alpha) + \ldots$$
$$= \sum_{n=1,3,\ldots} b^{\frac{n-1}{2}}\cos n(t+\alpha)$$
$$\mathrm{E} = \text{even series} = \frac{2x_2}{H}$$
$$= 1 + 2b\cos 2(t+\alpha) + 2b^2\cos 4(t+\alpha) + \ldots$$
$$= 1 + \sum_{n=2,4,\ldots} 2b^{\frac{n}{2}}\cos n(t+\alpha)$$
$$b = \frac{\sqrt{x_q''} - \sqrt{x_d''}}{\sqrt{x_q''} + \sqrt{x_d''}} = \frac{x_2 - x_d''}{x_2 + x_d''}$$

The short circuit torque is expressed in terms of the components of armature current and rotor excitation in the direct and quadrature axes. The expression in finite trigonometric form is

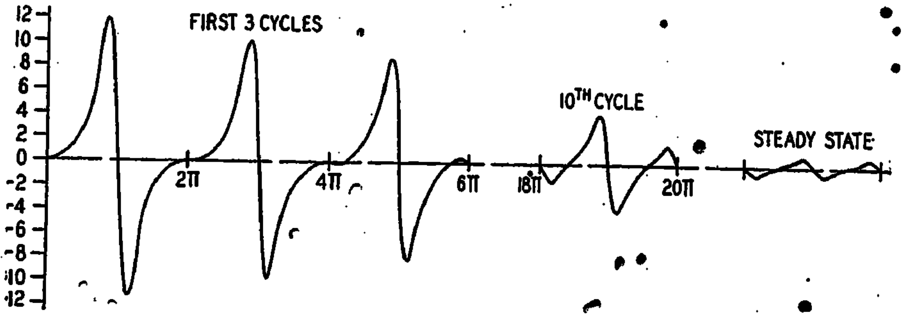

Fig. 1. Single-phase short-circuit torque of a 100,000-kva alternator, maximum initial armature linkages

$$\text{Torque} = -\frac{2F(F\cos t - A)\sin t}{H} - \frac{0.438(F\cos t - A)^2\sin 2t}{H^2}$$
$$= 5.25\,FA\,(\sin t + 0.669\sin 3t + 0.249\sin 5t + \ldots) -$$
$$(3.21\,F^2 + 1.92\,A^2)(\sin 2t + 0.446\sin 4t + 0.149\sin 6t + \ldots)$$
$$F = 0.449 + 0.417\epsilon^{-0.0021t} + 0.134\epsilon^{-0.060t}$$
$$A = \epsilon^{-0.025t}$$
$$H = 0.515 - 0.219\cos 2t$$

$$T = -\frac{2e_o^2F[F\cos(t+\alpha) - A]\sin(t+\alpha)}{H} + \frac{2e_o^2(x_d'' - x_q'')[F\cos(t+\alpha) - A]^2\sin 2(t+\alpha)}{H^2} \tag{5}$$

For the case of zero initial armature linkages, $\alpha = \pi/2$ and the above expression reduces to

$$T = \frac{2e_o^2x_q''F^2\sin 2t}{H^2} \tag{6}$$

The torque, expressed as the sum of odd and even harmonic series, is

$$T = \frac{e_o^2}{x_2 + x_d''}\left\{2FA\sum_{n=1,3,\ldots} nb^{\frac{n-1}{2}}\sin n(t+\alpha) - \left[F^2\frac{x_2}{x_2+x_d''} + A^2\frac{x_2 - x_d''}{x_2}\right]\sum_{n=2,4,\ldots} nb^{\frac{n-2}{2}}\sin n(t+\alpha)\right. \tag{7}$$

## SUMMARY OF RESULTS

The per-unit single-phase short-circuit torque is

$$T = \frac{2FAe_o^2}{x_2 + x_d''}\{\sin(t+\alpha) + 3b\sin 3(t+\alpha) + 5b^2\sin 5(t+\alpha) + \ldots\} - \frac{e_o^2}{x_2+x_d''}\left[F^2\frac{x_2}{x_2+x_d''} + A^2\frac{x_2 - x_d''}{x_2}\right]\{2\sin 2(t+\alpha) + 4b\sin 4(t+\alpha) + 6b^2\sin 6(t+\alpha) + \ldots\} \tag{8}$$

From an inspection of this equation it appears that the odd harmonic components of torque are due to the interaction of rotor and armature magnetic fields and that these components disappear as the trapped armature linkages die out. For the case of a short circuit with zero initial armature linkages no odd harmonic torques are present.

A part of the even harmonic torque is proportional to the square of the armature linkages and this part disappears when the subtransient reactances in the direct and quadrature axes are equal. This may be considered as a "reluctance torque" due to the variation in the permeance which the rotor offers to the trapped armature flux. Likewise, the part of the torque which is proportional to the square of the rotor linkages is due to the variation in the permeance which the armature offers to the rotor flux.

It is interesting to note that immediately after a short circuit with maximum armature linkages, the maximum value of second harmonic torque due to the field linkages alone is $x_2/(x_2 + x_d'')$ times the maximum fundamental torque, while the maximum value of second harmonic torque due to armature linkages alone is $(x_2 - x_d'')/x_2$ times the maximum fundamental torque. The maximum value of total second harmonic torque just after a short circuit with maximum armature linkages is $(2x_q'' - x_d'')/(x_q'' + x_2)$ times the maximum value of fundamental torque. This ratio varies from 0.5 for $x_d'' = x_q''$ to 1.25 for $x_d'' = 0.2\, x_q''$. Thus the maximum values of fundamental and second harmonic torque are of comparable magnitude just after short circuit.

Since the armature linkages eventually disappear, the steady state torque is made up entirely of even harmonic components.

### EXAMPLE OF CALCULATIONS

To illustrate the use of the formulas developed, numerical results have been calculated for a 60-cycle testing generator rated at 100,000 kva. The per unit constants of the machine, as determined by test, are as follows:

$x_d = 0.615$; $x_d' = 0.207$; $x_d'' = 0.148$
$x_q = 0.412$; $x_q' = 0.412$; $x_q'' = 0.367$
$\sigma_a = 0.025$; $\sigma_f' = 0.0021$; $\sigma_f'' = 0.069$

($x_q$ = quadrature axis synchronous reactance; $x_q'$ = quadrature axis transient reactance)

Hence $x_2 = 0.233$; $b = 0.223$

Figs. 1 and 2 show the line-to-line short-circuit torque with maximum initial armature linkages and zero initial armature linkages, respectively, as computed from the formulas derived.

From the standpoint of mechanical design of the machine and its foundations, the condition which gives maximum torque is the most important. It is evident that for this purpose it is sufficient to consider the torque with maximum initial armature linkages. In the case of the machine considered, the peak value of torque under this condition is nearly 12 times full load torque. It is to be noted that this high peak value is largely due to the presence of trapped armature linkages, since with no armature linkages the peak value of torque is only 4 times normal.

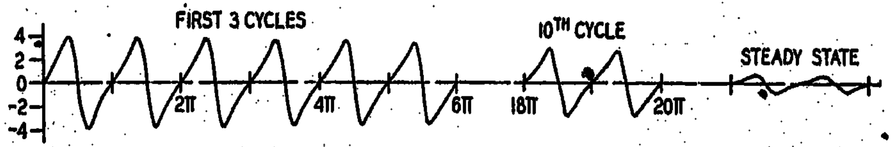

**Fig. 2. Single-phase short-circuit torque of a 100,000-kva alternator, zero initial armature linkages**

$$\text{Torque} = \frac{0.734\, F^2 \sin 2t}{H^2}$$

$$= 3.21\, F^2 (\sin 2t - 0.446 \sin 4t + 0.149 \sin 6t - \ldots)$$

$$F = 0.449 + 0.417\epsilon^{-0.0021\,t} + 0.134\epsilon^{-0.069\,t}$$

$$H = 0.515 + 0.219 \cos 2t$$

The trapped armature linkages are also responsible for all odd harmonic components of torque. Fig. 2 shows that with no trapped armature linkages the torque is made up entirely of even harmonics and in Fig. 1 it is seen that the odd harmonics decay gradually so that the torque curve approaches that of Fig. 2.

It appears from the eqs 5, 6, and 7 that the short circuit torque is the same for line-to-line and line-to-neutral short circuits. This is exactly true for an ideal machine and is true for actual machines provided that $x_0/2$ is negligible in comparison with $x_d''$ and $x_q''$ ($x_0$ = zero sequence reactance). Although the armature currents resulting from the two types of short circuit of an ideal machine are different, the armature mmfs are the same.

The consideration of machine losses would somewhat modify the torque as calculated in this article. The correction for losses can be calculated approximately in a given case, but this correction is generally small enough to be neglected.

# Motorized Pumps for Fuel Oil Trucks

INCREASING popularity of modern oil burners for heating purposes has resulted in a greatly increasing demand for fuel oil. Distribution of oil suitable for heating always has been a perplexing problem for this heavy oil must be pumped from the delivery vehicle to the customer's tank, even though the tank is below the level of the vehicle.

The delivery problem has been somewhat simplified and the delivery time greatly reduced by the Suburban Fuel Oil Service, Inc., Mount Vernon, N. Y., by replacing the mechanical pump drive with an electrical drive on one of its trucks, a 21-ton 6-wheel tractor-trailer type with a capacity of 3,000 gal. Originally the centrifugal pump with which this truck was equipped was mounted on the tractor; it was connected directly to a 4-speed power take-off on the transmission of the truck. In making a delivery 2 hoses had to be connected necessitating 4 hose connections in all.

In making the change to electrical drive, the pump was removed from the tractor and placed next to the tank on the left underside and is now driven through a silent chain drive by a 3-hp shunt motor. On the tractor the power take-off shaft was extended and, by means of a heavy duty silent chain, now drives a 3-hp

---

Prepared especially for ELECTRICAL ENGINEERING from information contributed by Mark W. Copeland (M'31) consulting engineer, Westchester Sign Display Company, Bronx, N. Y.

shunt generator. A small $1/4$-hp compound-wound generator mounted near the main generator and driven by the power take-off shaft with a V belt, supplies constant field current to the motor and, through a specially designed rheostat, supplies variable field current to the generator. This rheostat provides the only control necessary both to start and stop the motor, and to vary the pump speed from about 15 to 375 rpm, its maximum rated speed. For the "off" position this rheostat circuit is simply opened, the armatures of the motor and generator being solidly connected together through a circuit breaker. With this arrangement but small currents, rarely exceeding 1 amp at 220 volts, are handled in the control circuit. Meters are provided to indicate directly (1) load in per cent of motor capacity, (2) pumping rate in gallons per minute, and (3) generator speed; the meter dials are illuminated for night operation.

Curves in Fig. 2 show delivery time before and after the pump was equipped for electrical operation; these are on the basis of 3,000-gal loads, with the number of deliveries per load plotted against time required for making hose connections and for pumping. In addition to the reduction in delivery time, the number of hose connections per delivery has been reduced from 4 to 1, the only connection necessary being that to the customer's tank. The truck has been in operation 24 hr per day for the past 8 months, without one failure. It is said to be the first and only truck equipped for pumping oil by this method.

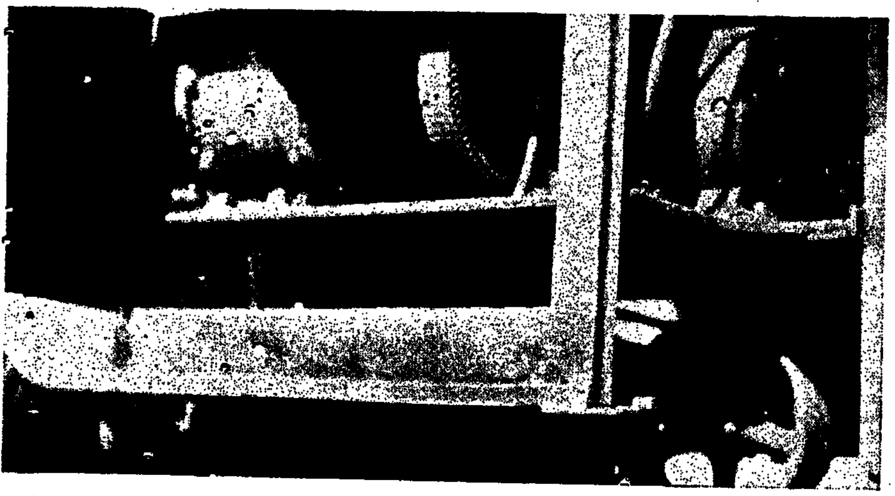

Fig. 1. View of electrically driven pump showing method of mounting

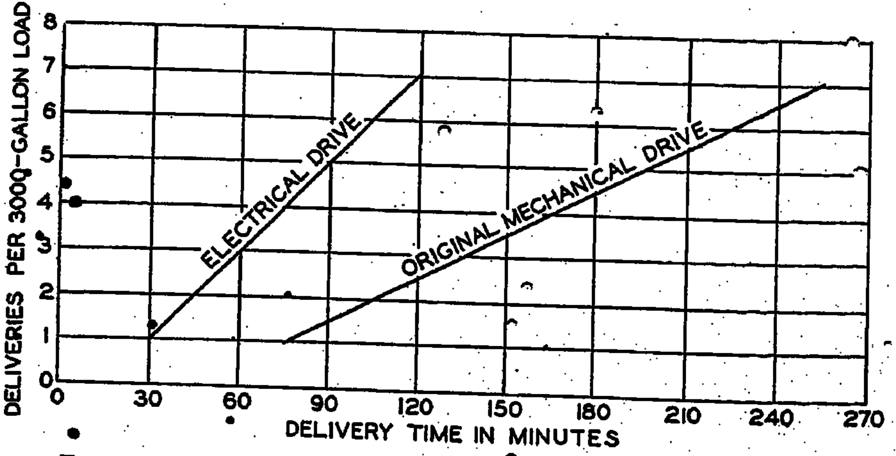

Fig. 2. Oil delivery time (No. 3 oil) before and after pump was equipped for electrical operation

Maximum pumping rate with original drive, 70 gpm; with electrical drive, 200 gpm

# Transformers With Peaked Waves

**Special purpose transformers now can be built to provide a secondary voltage wave less than 2 electrical degrees wide from a sinusoidal primary voltage source. The construction of such a transformer and some of its uses are described in this article.**

By
O. KILTIE
ASSOCIATE A.I.E.E.

General Elec. Co.
Fort Wayne, Ind.

ONE OF THE MOST RECENT developments in transformer design is that of a transformer with an extremely narrow secondary voltage wave. A peaked secondary voltage wave transformer may be defined as a transformer providing a narrow secondary voltage wave from a sinusoidal primary voltage source. The minimum width of wave thus far obtained is between 1 and 2 electrical degrees measured at $1/2$ of the maximum amplitude. However, the transformer can be designed for almost any width of wave above this value up to a limit of approximately 90 electrical degrees. These transformers have been produced during the last few years and are now available for commercial application.

Transformers of this type originally were designed and developed for stroboscopes in 1927 by C. A. Nickle (General Electric Company, Schenectady, N. Y.); in 1928 they were applied to thyratron (a grid controlled mercury vapor tube) inverter circuits. Since that time these transformers have been found to serve very well as component parts of frequency meters and tachometers.

Design of these transformers is somewhat different from that for other transformers. One of the vexing problems during the past with saturated type transformers has been the inherently high primary burden required from the supply source. This has been partially overcome by the present method of construction and the selection of material.

It is quite possible to obtain the required secondary voltage by using different methods of construction, but the most desirable method from the manufacturing point of view is that shown by Fig. 1. Before proceeding with the details of construction and operation, however, an explanation should be made of the fundamental object in the design. It is desired to

---

Written especially for ELECTRICAL ENGINEERING, based upon a presentation before the A.I.E.E. Fort Wayne, Ind., Section, April 14, 1932. *Not published in pamphlet form.*

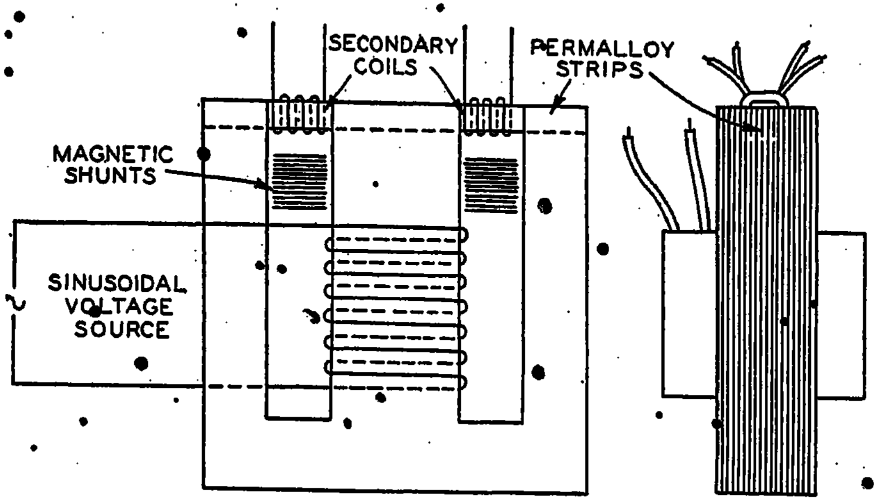

Fig. 1. Construction details of a transformer for peaked secondary voltage waves

saturate the secondary core section to a certain degree depending upon the required width of secondary voltage wave. With this condition the core section for the primary winding should not be saturated. To produce the peaked secondary voltage the secondary core material must possess a very steep magnetization curve below the knee, and beyond the knee it should be as nearly a horizontal line as possible. Permalloy (an alloy of nickel and iron) properly heat treated satisfies these requirements best.

In the type of construction shown in Fig. 1, the main core is comprised of the economical type of "E" punchings; these punchings are made from regular silicon steel, a material which can be operated at a flux density just below saturation. The primary coil is assembled onto the center leg of the core. Laminated magnetic shunts of the proper cross-section and length to permit a low reluctance are placed in each "window" between the primary and secondary coils. It is necessary that these shunts be of proper dimensions so that they will pass all of the flux not forced through the permalloy secondary core section for reasons explained later. In attempting to obtain the narrowest waves, permalloy strips 0.014 in. thick originally were used; these were placed across the open end of the "E" punchings. Later it was found that for a given cross-section of permalloy 0.0045-in. laminations produced a narrower wave than laminations of 0.014-in. thickness. However, unless an extremely narrow wave is essential the 0.0045-in. material should not be used, because of its more delicate and expensive character.

By making its cross-sectional area much less than that of the silicon steel, the permalloy core section must become saturated very quickly, providing the silicon steel section is operating at a density just below the knee of its magnetization curve. Since the magnetization curve for permalloy is quite flat after saturation is reached it is possible to keep the zero portion of the secondary voltage to a straight line. This portion of the wave must be held to zero throughout the entire period of time between alternate secondary peak waves, in order to meet the requirements of certain practical applications of the transformer.

From Fig. 2 it can be seen that the width of the secondary voltage wave is dependent upon the extent of magnetization of the permalloy core section or upon the amplitude of the secondary flux wave $\Phi_{sec}$. During the saturated period there is no change of flux; consequently, the secondary voltage must be 0 during that period. The flux changes rapidly from the positive saturated condition to the negative saturated condition producing a peaked voltage wave, which is equal in width to the angle $\theta$. If the air-gap be too large or the secondary coil build too high, there will be a fringing of flux through the coil; this flux cannot pass through the permalloy because of its saturated condition. As a result the peaked voltage will contain a superimposed sine wave component voltage, the amplitude of which possibily could be a considerable fraction of the maximum amplitude of the peaked voltage wave. Obviously, it is advisable to avoid this component.

Extremely narrow waves could be obtained more easily by using a primary flux wave having a flat top and very steep sides; this is because the flux changes more rapidly in a wave of that sort than in a sine wave. Such a flux wave could be obtained by using an additional transformer between the source of supply and the peaked voltage transformer.

Wave shapes of the peaked voltage transformers have decidedly good features such as steep sides, flat top, and a straight line zero portion. As one might expect, they do not take the shape of a "saw tooth" or of a wave having a form factor of approximately 1.6. The true shape can be seen from Fig. 2, and from actual oscillograms reproduced in Fig. 3. Variations in the supply voltage alter the width of the wave but slightly.

The burden taken by a transformer having a 2° wave required only 0.15 amp exciting current and 1.5 watts at 110 volts and 60 cycles; if necessary, even this small burden can be reduced. Characteristic curves for a typical transformer under different conditions are shown in Fig. 4.

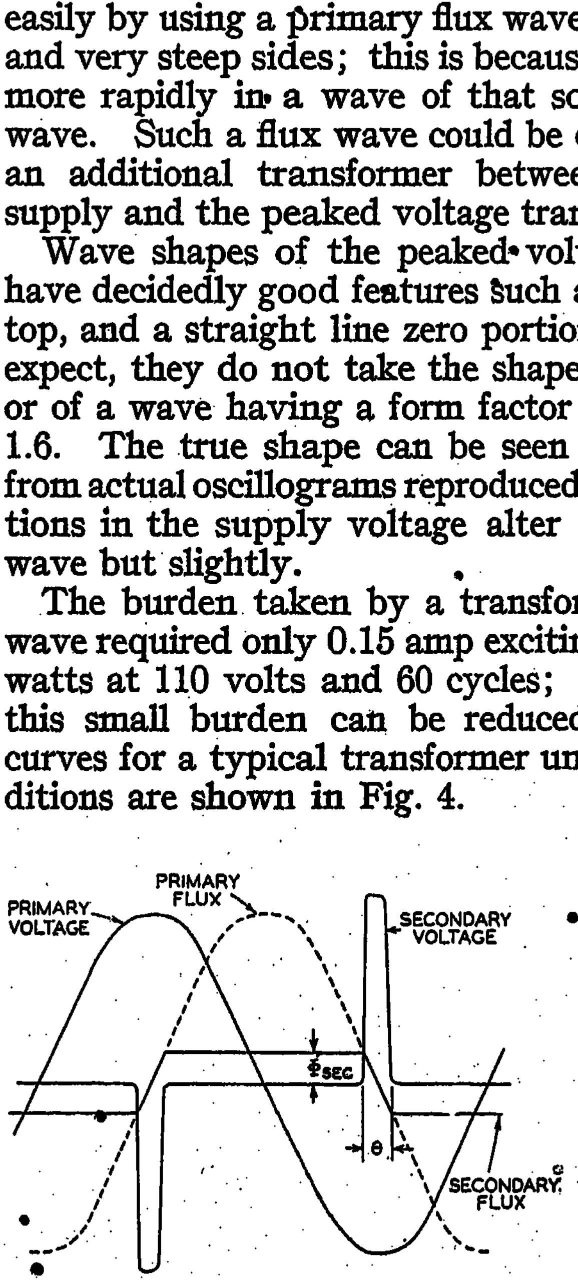

Fig. 2. Voltage relations in the peaked-voltage transformer

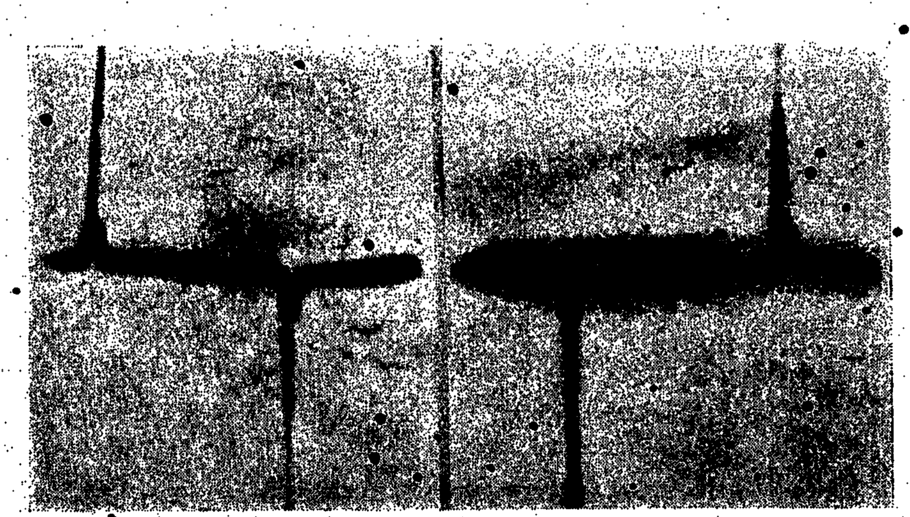
Fig. 3. (Below) Oscillograms of the transformer secondary voltage



100-volt 60-cycle waves approximately 3° wide (left) and 10° wide (right) at half maximum amplitude

Recognition should be given to B. D. Bedford (General Electric Company, Schenectady, N. Y.) for his original work on this type of transformer and for his valuable suggestions during the development.

## Uses for the Peaked Voltage Transformer

As mentioned previously, one of the earliest applications of the peaked secondary voltage wave transformer was in inverter circuits using the grid-controlled mercury vapor tube. A peak voltage is essential for excitation circuits of this tube for several reasons:

1. In certain circuits peaked excitation causes the phase position of the initial excitation to be independent of the time the switch is closed.

2. In many tube circuits the excitation period must be short. For example, in inverter circuits the excitation period of a tube should be at least as short as its conducting period.

3. A very steep wave front for grid excitation has the advantage over other wave forms since any change in grid potential or tube characteristics will have small effect on the time of excitation.

4. In frequency changers using this tube the low frequency excitation may be used to turn on and off the high frequency excitation by means of a transformer with a peaked secondary voltage wave.

Since many new circuits for the grid controlled mercury vapor tube are being developed continually, it is thought that this type of transformer will be used extensively in this field because it can serve as an essential component part in many of the circuits.

A combined transformer with peaked secondary voltage and neon lamp furnish the essential component parts of a good stroboscope. If the viewing is done through a narrow slot in the stroboscope disk, the width of the light spot on the disk will be dependent upon the width of the secondary voltage wave from the supply transformer. The spot will be very narrow with the use of a 5° voltage wave and also very sharp. Synchronous characteristics or the phase displacement between 2 voltage waves can be viewed readily and conveniently by this method.

It seems that there are many applications for a peaked voltage transformer with features for shifting the secondary voltage with respect to the primary voltage. This is especially desirable for certain tube applications such as frequency converters using the grid controlled mercury vapor tube, and polycyclic inverters. Several methods of obtaining the shifted peaked voltage have been used, but the following paragraphs illustrate one method which has been quite satisfactory.

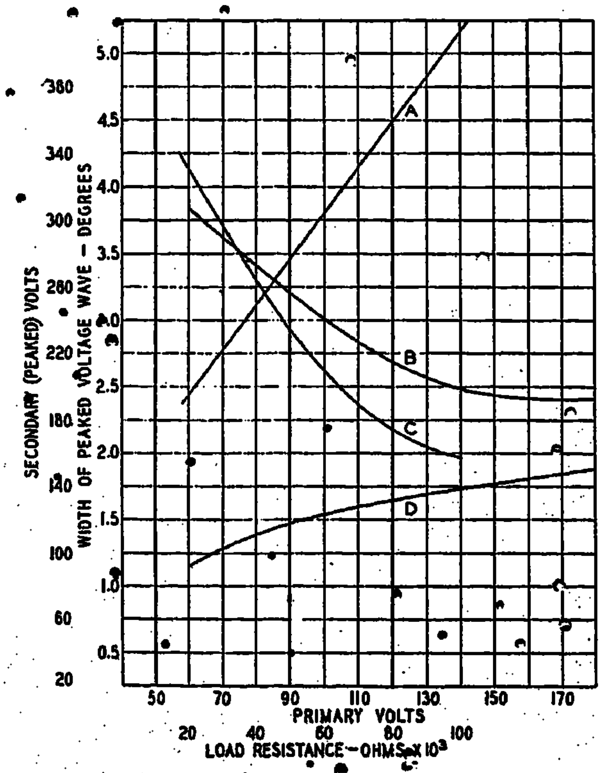


**Fig. 4. Characteristic curves for a typical transformer for peaked voltage**

A—Secondary peak volts vs primary volts
B—Width of wave vs load resistance
C—Width of wave vs primary volts
D—Secondary peak volts vs load resistance
Curves A, B, and C are for both secondary coils in series; Curve D is for one secondary coil with the other coil open (see Fig. 1)

Construction similar to that shown in Fig. 1 is used except that an auxiliary coil is added on the center leg of the core spaced between the magnetic shunts and 2 additional shunts placed next to the secondary coils, as shown in Fig. 5. It is possible to obtain shifts in one direction to a maximum of 135 electrical degrees. Several units were built having a 40-volt peaked wave with a width of approximately 4°, shifted only 90° away from the primary voltage instead of the usual 180°. Although a small shift can be obtained by connecting the auxiliary coil so that its mmf aids that of the main coil, the maximum shift is obtained by connecting this coil so that its mmf opposes that of the main coil, when both are connected to the same source of supply voltage. Some means of control must be used to vary the auxiliary coil mmf so that the desired variation in the angle of shift can be obtained. Best results are obtained by using a variable series resistor instead of an inductor or condenser to vary the amount of current in the auxiliary coil. It can be seen that the change of resistance in the one circuit varies the voltage across the auxiliary coil, and this is accompanied by a change of the magnetizing current in the primary coil. Such a combination causes the mmf's of the 2 coils to be out of phase with each other and to produce a fundamental mmf out of phase with the primary voltage. The permalloy section of the core of course conducts only the displaced flux and consequently the peaked secondary voltage is displaced accordingly from the primary voltage.

The burden required for such a device is not excessive. Those units of this type to which reference was just made required only 13.5 va at 90 volts and 50 cycles. With increases in phase shift the burden is increased, but it is quite probable that for most purposes a shift greater than 90° is not necessary. Amplitude, width of wave, and phase displacement of the peaked secondary voltage waves are not changed appreciably by large variations of the primary voltage.

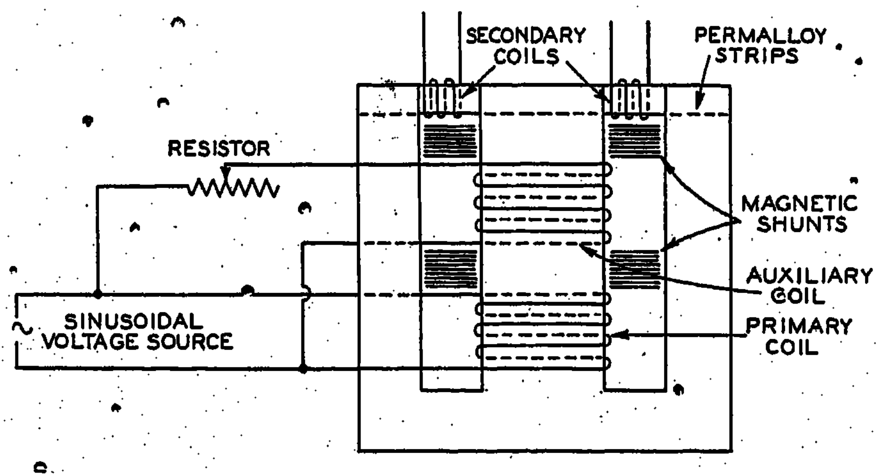

**Fig. 5. Construction of peaked-voltage transformer with provisions for shifting the phase relations of the secondary and primary voltages**

# Cables, Water Power, Dominate Baltimore Sessions

OF THE 4 regular sessions of the Middle Eastern District meeting held Oct. 10–13, 1932, at the Lord Baltimore Hotel in Baltimore, Md., one was given over to 4 papers dealing with power cables, one to 3 papers concerned with communication cables, and 2 to the presentation of 6 papers devoted to hydroelectric subjects including delivery and distribution of power so generated. Meeting jointly with the Institute for the first 2 (cable) sessions, was the National Research Council's committee on electrical insulation which functions under the leadership of Dr. J. B. Whitehead. This latter committee subsequently held 3 independent sessions in Maryland Hall on the Johns Hopkins campus, but otherwise participated in the general activities of the meeting. The Institute's board of directors also met in conjunction with the meeting, as reported elsewhere in this issue.

Analysis of Attendance at Baltimore

| Classification | Baltimore | Dist. No. 2 | Dist. No. 3 | Dist. No. 1 | Misc. | Totals |
|---|---|---|---|---|---|---|
| Members | 76 | 50 | 33 | 18 | 18 | 195 |
| Men Guests | 13 | 13 | 1 | 2 | 4 | 33 |
| Women Guests | 6 | 2 | 3 | 1 | 0 | 12 |
| Totals | 95 | 65 | 37 | 21 | 22 | 240 |

Registration totaled 240, classified as indicated in the accompanying tabulation, a turn-out that paid tribute to the general interest value of the technical program presented by the Baltimore meeting committee. Further response to the program's appeal was evidenced by the attendance at the individual sessions, ranging from 125 to 180, and by the discussions, which were distinctly above the average in quality and in quantity. The various activities which were coordinated during the 3 days of the meeting evidently exerted a favorable influence upon the attendance from points relatively remote from Baltimore.

### Technical Sessions

Allowing Monday morning, for the convenience of late arrivals, for registration, and for a District executive committee meeting (reported elsewhere in this issue) the technical sessions were held Monday afternoon, Tuesday morning, and Wednesday morning and afternoon as outlined in the program published on p. 664 of Electrical Engineering for Sept. 1932. Presiding at these sessions were, respectively, Dr. J. B. Whitehead, dean of engineering at The Johns Hopkins University, Baltimore, Md.; J. L. D. Speer, Jr., chief engineer, Chesapeake & Potomac Telephone Company of Baltimore City, Md.; A. F. Bang, superintendent of operation, Pennsylvania Water & Power Company, Baltimore, Md.; and J. R. Baker, operating engineer, Pennsylvania Water & Power Company, Baltimore, Md.

Organized inspection trips provided for visits to points of timely interest in the vicinity of Baltimore. On Monday evening a group visited the plant of the Locke Insulator Company where, after a brief turn of inspection through the factory, a demonstration of an interesting and spectacular nature was staged in the company's 3,000,000-volt laboratory. One of the Tuesday afternoon trips included visits to 2 local steam-electric generating plants and to the Baltimore terminal substation of the Safe Harbor 230-kv transmission system. As an alternate to this trip, others visited the Western Electric Company's insulated wire mill and cable plant and the nearby factory of the General Aviation Company. All day Thursday was given over to a trip to the Safe Harbor hydroelectric plant of the Pennsylvania Water & Power Company. A special car was handled on regular Pennsylvania trains between Baltimore and Perryville, Pa., then to and from the plant by a special locomotive. Ample time was available for a thorough inspection of the plant and all of its associated structures. Luncheon was served at the plant by the power company.

### Entertainment

Entertainment features provided were simple in character, but nicely rounded out the meeting program. Women guests were taken Tuesday afternoon to the United States Naval Academy at Annapolis where they were shown the sights and subsequently served with tea at Carvel Hall. An informal sight-seeing trip and tea also were provided for the women Wednesday afternoon.

At an informal gathering Tuesday evening, with Dr. W. B. Kouwenhoven, A.I.E.E. vice-president for the Middle Eastern District, presiding, President Charlesworth presented certificates and prizes to W. P. Taylor of Baltimore who won both the initial-paper prize and the best-paper prize for his District for 1931 as reported on p. 418 of Electrical Engineering for June 1932. Subsequently called upon to address the gathering, President Charlesworth gave public recognition of the work done by the personnel of the local meeting committees, and spoke briefly upon Institute affairs in general. He called attention to the fact that the Institute for more than 48 years has devoted its efforts to the furtherance of the ideal laid down by its founders in 1884: "the advancement of the theory and practice of electrical engineering and of the allied arts and sciences, the maintenance of a high professional standing among its members, and development of the individual engineer." President Charlesworth also outlined briefly the various successive steps in broadening the Institute's services to its members—through the formation and development of local Sections and subsequently of Student Branches, and in recent years the extension of regional activities including District conventions. Current problems came up for brief mention, too, as he cited the efforts of the finance committee and the headquarters staff in attempting to meet the rigorous requirements of a substantially reduced budget without impairment to the Institute's more important services to its members. President Charlesworth bespoke support and cooperation for the national officers and the office staff in their efforts to cope with the present situation. Following this, Dr. Adolph H. Shultz, associate professor of physical anthropology at The Johns Hopkins University, delivered an enlightening and challenging illustrated lecture, "Man as a Primate," in which he presented excerpts from a mass of data revealing close similarities between man and the higher forms of anthropoids, notably the orang-utan, the chimpanzee, and the gorilla.

Culminating the social activities of the Baltimore meeting was the dinner-dance held at the Lord Baltimore Hotel, Wednesday evening.

# November 15 Last Date for Suggesting Nominations

Actions specified in the Institute's constitution and by-laws relative to the organization of a national nominating committee are being taken, and the meeting of the national nominating committee for the nomination of officers to be voted upon at the election in the spring of 1933 will be held between November 15 and December 15, 1932. All suggestions for the consideration of the national nominating committee must be received by the secretary of the committee at Institute headquarters, New York, N. Y., not later than November 15, 1932.

## A.I.E.E. Directors Meet at Baltimore

A regular meeting of the board of directors of the American Institute of Electrical Engineers was held at the Lord Baltimore Hotel, Baltimore, Md., on Wednesday, October 12, 1932, during the Institute's Middle Eastern District meeting.

Present were: *President*—H. P. Charlesworth, New York, N. Y.; *Past-presidents*—W. S. Lee, Charlotte, N. C.; C. E. Skinner, East Pittsburgh, Pa.; *Vice-presidents*—W. W. Freeman, Lexington, Ky.; J. Allen Johnson, Buffalo, N. Y.; W. B. Kouwenhoven, Baltimore, Md.; P. H. Patton, Omaha, Neb.; *Directors*—L. W. Chubb, East Pittsburgh, Pa.; A. B. Cooper, Toronto, Ont.; B. D. Hull, Dallas, Tex.; A. E. Knowlton, New York, N. Y.; G. A. Kositzky, Cleveland, Ohio; A. H. Lovell, Ann Arbor, Mich.; F. W. Peek, Jr., Pittsfield, Mass.; C. E. Stephens, New York, N. Y.; A. C. Stevens, Schenectady, N. Y.; H. R. Woodrow, Brooklyn, N. Y.; *National treasurer*—W. I. Slichter, New York, N. Y.; *Acting national secretary*—H. H. Henline, New York, N. Y.

The minutes of the board's meeting held August 2, 1932, were approved.

A memorial resolution was adopted in memory of Dr. C. O. Mailloux, a charter member and past-president of the Institute, who died on October 4, 1932. This resolution is published elsewhere in this issue.

A report of a meeting of the board of examiners held September 28, 1932, was presented and approved. Upon the recommendation of the board of examiners, the following actions were taken upon pending applications: 6 applicants were transferred to the grade of Fellow; 6 applicants were elected and 30 were transferred to the grade of Member; 38 applicants were elected to the grade of Associate; 138 Students were enrolled.

The following resolution was adopted:

> WHEREAS, death has suddenly removed Colonel Basil C. Battye, D.S.O., A.M., Local Honorary Secretary for India of the American Institute of Electrical Engineers, be it
>
> RESOLVED: That the board of directors at its meeting of October 12, 1932, places this minute on record as an appreciation of the loyal and devoted service which Colonel Battye gave to the Institute as its official representative in India. His thorough understanding of conditions in India, and his able judgment have served as an unfailing guide to our board of examiners through many otherwise perplexing problems.

The resignation of George A. Mills as a vice-president of the Institute, representing the South West District, on account of his removal from that District, was presented; and Stanley Stokes, consulting electrical engineer of the Union Electric Light and Power Company, St. Louis, Mo., and a Fellow of the Institute, was elected vice-president of the Institute for Mr. Mills' unexpired term, ending July 31, 1934.

The following members of the Board of Directors were selected to serve on the national nominating committee for this year: A. B. Cooper, A. E. Knowlton, W. S. Lee, A. C. Stevens, and H. R. Woodrow.

The Institute's representative upon the joint committee of engineers and architects was discharged, report having been made of the completion of the committee's work.

A report was received from Chairman F. B. Jewett of the Institute's committee on Iwadare Foundation, to the effect that the committee had arranged for Dr. Frank J. Sprague, a past-president of the A.I.E.E., to lecture in Japan this fall under the Iwadare Foundation.

Institute representatives were appointed as follows:

**On Standards Council, American Standards Association.**—A. M. MacCutcheon was reappointed a representative for the 3-year term beginning January 1, 1933, and H. H. Henline and E. B. Paxton were reappointed alternate representatives for the calendar year 1933. H. S. Osborne was designated as the chairman of the Institute's representation on the standards council.

**On Engineering Foundation Board.**—Past-president C. E. Skinner was reappointed for the 3-year term beginning in February 1933.

**On Library Board, United Engineering Trustees, Inc.**—W. A. Del Mar was reappointed for the 4-year term beginning in January 1933.

**On Board of Trustees, United Engineering Trustees, Inc.**—President H. P. Charlesworth was reappointed for the 3-year term beginning in January 1933.

The following actions were taken upon the recommendation of the standards committee:

Approved a revision of Section 4-102 of A.I.E.E. Standard No. 4, "Measurement of Test Voltages in Dielectric Tests," as suggested by the committee on electrical machinery.

Approved a revision, proposed by the committee on electrical machinery, of A.I.E.E. Standard No. 13 on "Transformers, Induction Regulators, and Reactors," and referred it to the sectional committee on transformers being organized under the sponsorship of the electrical standards committee of the American Standards Association.

Adopted a recommendation in favor of a proposed revision of the present A.I.E.E. Standard No. 14, "Instrument Transformers," for reference to the sectional committee on electrical measuring instruments which is being organized under the sponsorship of the electrical standards committee of the A.S.A.

Approved, as a joint sponsor, the revised "Code for Protection Against Lightning" as prepared by the sectional committee on that subject.

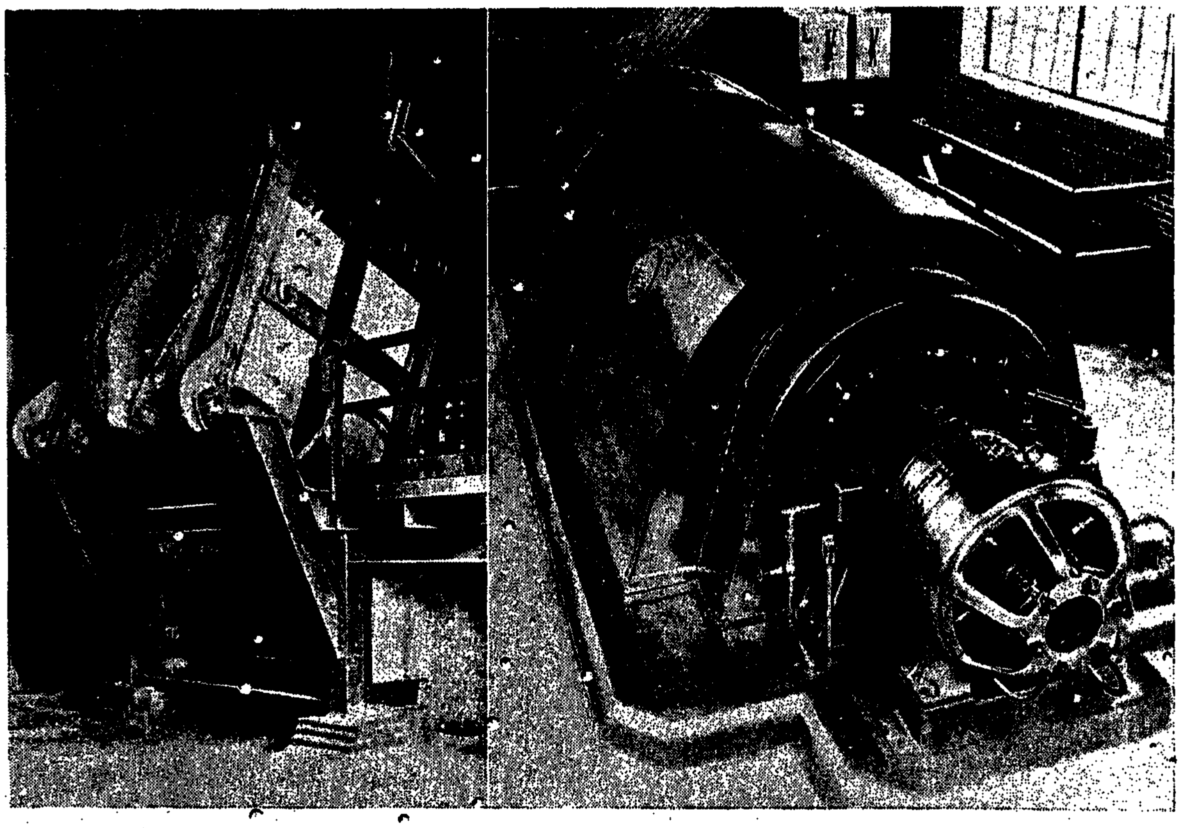
Granted permission to the U.S. Department of Commerce to publish the A.I.E.E. standards in the *Encyclopedia for Standards and Specifications.*

Granted permission to the Asociacion de Ingenieros del I.C.A.I. to reprint the Institute standards in the Spanish language.

A resolution was adopted decreasing the number of meetings of the board of directors during the year beginning October 1, 1932, in order to reduce expenditures for traveling expenses; meetings of the executive committee to be substituted at the discretion of the president. In line with this action

---

## A 4-Ton Coreless Induction Furnace



During the fall of 1931 a 4-ton coreless furnace capable of melting 40 to 50 tons per day was put in operation in the Chicago district. This is almost double the size of any coreless melting furnace previously installed. The main purpose of the furnace is to melt low carbon stainless steep scrap, also ferro-alloys for addition to larger furnaces, and metal for ingots of high quality tool steel and other alloys. The coreless induction furnace is essentially an air transformer whose primary is a single helical layer of water cooled copper tubing, and whose secondary within the coil is a conducting mass constituting the charge to be melted. Induced currents circulate in the outer part of the charge, and thereby heat it. The furnace, tilted for pouring, is illustrated on the left, and the 1,000-cycle motor generator set is shown on the right. The use of structural steel in the construction of the furnace is more extensive than in any previous installation. Another distinguishing feature of this installation is the carrying of 12,000 amp at 1,000 cycles by means of water cooled tubing interlaced to cut down inductance.

it was voted that the December meeting of the board be omitted and that the next meeting be held in New York, in January, during the Institute's winter convention.

Also because of economic conditions, the board voted to omit the publication of a YEAR BOOK in 1933 and to omit the cash prizes for papers presented in the calendar year 1932, except the District prizes for Branch papers; the certificates for all prizes to be issued as usual.

A budget for the appropriation year of the Institute beginning October 1, 1932, submitted by the finance committee, was adopted with minor revisions.

The board adopted a resolution of congratulation to the local meeting committees upon the excellent results of their efforts in connection with the Middle Eastern District meeting of the Institute, held at Baltimore, October 10–13.

Other subjects were discussed, reference to which may be found in this or future issues of ELECTRICAL ENGINEERING.

## District No. 2 Officers Meet at Baltimore

Preceding the first technical session of the Middle Eastern District meeting held at Baltimore, October 10–13, 1932, the executive committee of that district met Monday morning, October 10, with Dr. W. B. Kouwenhoven, district vice-president, presiding. Every one of the 12 sections in the district was represented and the attendance was full, as indicated in the accompanying tabulation, with the exception of the Student Branch counselor member. Extensive routine District business and discussions of matters of policy kept the committee in session all morning, after which the committee adjourned to an informal luncheon from which they went directly to the opening technical session. Present were:

H. P. Charlesworth, President, A.I.E.E. (visitor)
W. B. Kouwenhoven, Vice-president, District No. 2
Geo. S. Diehl, Secretary, District No. 2
H. H. Henline, Acting Nat. Secy., A.I.E.E.
C. E. Skinner, Past-president, A.I.E.E. (visitor)
A. P. Regal, Section Chairman, Akron, Ohio
John Wells, Section Chairman, Baltimore, Md.
L. O. Dorfman, Section Chairman, Cincinnati, Ohio
John M. Smith, Section Chairman, Cleveland, Ohio
W. L. Everitt, Section Delegate, Columbus, Ohio
C. V. Roberts, Section Secretary, Erie, Pa.
N. S. Hibshman, Section Delegate, Lehigh Valley
J. L. MacBurney, Section Secy., Philadelphia, Pa.
Thomas Spooner, Sec. Chairman, Pittsburgh, Pa.
A. P. Bender, Section Chairman, Sharon, Pa.
I. H. Heitkamp, Section Chairman, Toledo, Ohio
T. J. MacKavanagh, Sec. Chmn., Washington

In accordance with the requirement in article VI of the constitution, Prof. A. M. Wilson (A'09–M'18) professor of electrical engineering at the University of Cincinnati (Ohio) was nominated for the office of vice-president of the Institute representing District No. 2 for the 2-year term beginning August 1, 1933. To represent District No. 2 on the national nominating committee, which probably will hold its meeting some time early in December, John Wells (A'27) development engineer for the Western Electric Company, Baltimore, and chairman of the Baltimore Section (1932–33) was appointed and given instructions.

To form, in accordance with section 33 of the by-laws, "A small continuously functioning coordinating committee" Thomas Spooner (F'29) of Pittsburgh, John M. Smith (A'24) of Cleveland, L. O. Dorfman (M'28) of Cincinnati, and T. J. MacKavanagh (M'13) of Washington, D. C., were appointed from the executive committee and Prof. Lewis Fussell (M'22) Professor of electrical engineering of Swarthmore, (Pa.) College representing the student branch counselors, were elected to serve with the district vice-president and secretary.

To serve District No. 2 for the year 1932–33 a District prize award committee was appointed, consisting of Dr. H. L. Curtis (A'21–F'26) Washington, D. C., A. P. Bender (A'18) Sharon, Pa., and Prof. S. S. Seyfert (M'13) Lehigh University, Bethlehem, Pa. Dr. Curtis will serve as chairman of this committee.

Concerning future district meetings for the Middle Eastern District, and their financing, there was considerable discussion. Concerning the matter of finance, the concensus of opinion was to the effect that all sections in the district should bear a reasonably proportionate share of the expense of holding each district meeting, regardless of where it may be held; the group decided to continue the present plan of requesting each section to pay an assessment of $10 plus 10 cents per member in that section as of August 1. The question of a meeting for 1934 was discussed, but no requests for such meeting were voiced and no recommendations were made.

## Winter Convention Committee Appointed

The general convention committee in charge of arrangements for the coming annual winter convention of the Institute which is to be held in the Engineering Societies Building, New York, N. Y., January 23–27, 1933, has been appointed by President Charlesworth. Plans for the various events which are to comprise this convention are assuming definite form, a tentative program of technical sessions has been made, and the preparation of papers for these sessions is well under way.

As members of the general convention committee President Charlesworth has appointed the following: *chairman*, E. B. Meyer (F'27) vice-president District 3; J. W. Barker (F'30) member, technical program committee; T. F. Barton (F'30) chairman, New York Section; F. M. Farmer (F'13) member, research, and power transmission and distribution committees; W. H. Harrison (F'31) chairman, technical program committee; L. W. W. Morrow (F'25) Institute representative on Engineers' Council for Professional Development; C. E. Stephens (M'22) director, and chairman, finance committee; H. R. Woodrow (F'23) director, and C. R. Jones (A'16,M'30) secretary District 3.

Ample material is available for the technical sessions, and these include a wide range of subjects in the field of electrical engineering. Special plans are being made for the communication session and these tentatively provide for the presentation of 5 papers on the communication system of railroads. Tentative plans of the committee on education provide for a symposium on post college education. The electrical machinery committee also is making special plans, and these include the holding of an informal session on noise. At some other sessions presentation of manuscripts without publication and without distribution of advance copies is being considered.

Subjects tentatively under consideration for technical sessions are: communication, electric welding, automatic stations, electrical machinery, transportation, education, industrial applications, lightning, electrochemistry and electrometallurgy, instruments and measurements, applications to mining work, protective devices, selected subjects and, research and applied electronics. Detailed plans for the technical sessions, social features, and inspection trips will be announced in future issues of ELECTRICAL ENGINEERING.

## Generation Committee Plans New Papers

Capitalizing upon the opportunity presented by the recent Middle Eastern District Meeting held at Baltimore, Md., October 10–13, 1932, Chairman J. R. Baker called a meeting of his committee on power generation on October 12.

To orient the committee, the activities during the past 4 years were reviewed and the papers produced on the general subject of electric power generation were listed in 3 groups according to classification of subject matter: (1) steam-electric production, (2) hydroelectric production, and (3) utilization of sources of power supply by means of interconnection. According to their types these papers were segregated further into such classifications as plant descriptions, analytical discussions, and reports of experimental work. There have been 23 papers on the subject of steam-electric generating plants, 16 concerning hydroelectric practise, and 18 dealing with various phases of interconnection.

Of the 3 subjects mentioned in the foregoing paragraphs 2 were considered to have been fully reported upon to date and to have been adequately described and analyzed for the present: developments in hydroelectric practise, and matters pertaining to interconnection. Recent progress in the field of steam-electric power production was considered to be of timely importance and to be a desirable subject for a paper to be presented in the near future, so as to call attention to profitable lines of design. Possible sources of such a paper were discussed; 2 plants now under construction were considered as exemplifying present trends, one in initial design and the other as a splendid example of rehabilitation.

Electrical testing of welded pressure vessels came up for consideration and specifications were discussed for a suitable paper relating to that subject that might be presented in conjunction with one already on hand concerning the economics of high pressure and high temperature. The committee gave attention to the difficulty of giving a complete understanding of advances in power generation without elaborating too deeply upon the features of mechanical design. Plans also were made for a paper that would describe the electrical system adopted in a large plant recently placed in operation in which both a 60-cycle and a 25-cycle electric power supply were demanded. Other subjects to be initiated will concern safety devices in electrical operation, automatic turbine control through remote metering, and power control at generating stations. A subcommittee was established to handle a contemplated progress report covering the present biennial period.

## Birmingham Section Reorganization Announced

A meeting of the Birmingham Section of the Institute was held on September 30, 1932, for the purpose of discussing future plans and reorganizing the Section. The meeting took place in the Tutwiler Hotel, the reported attendance being 17 Institute members and 1 Student member. F. C. Weiss (M'19) acted as presiding officer.

Following a discussion of various schemes to best serve the Birmingham Section, an organization was formed to carry on the Section's business and maintain a nucleus around which additional activities can be added as the occasions demand. The new chairman is Howard Duryea (A'11) Commonwealth & Southern Corporation, Birmingham, Ala., and the new secretary is H. M. Woodward (M'29) Southern Bell Tel. & Tel. Company, Birmingham, Ala. The following were named as the executive committee: Prof. F. R. Maxwell (M'30) University of Alabama, Tuscaloosa, Ala., Prof. W. W. Hill (M'24) Alabama Polytechnic Institute, Auburn, Ala., and W. W. Ballew (M'28) Westinghouse Elec. & Mfg. Co., Birmingham, Ala. With the organization of the Birmingham Section, the present list of Institute Sections is made complete.

## District No. 8 Officers Meet at San Francisco

With Pacific District Vice-President A. W. Copley in the chair, the executive committee of the Pacific District held its annual meeting at the Engineers' Club in San Francisco September 7, 1932. With the exception of A. P. Hill, secretary of the Los Angeles Section, all members were present; in addition to the chairman were:

C. E. Baugh, secretary, District No. 8.
F. E. Dellinger, chairman, Los Angeles Section.
E. F. Maryatt, chairman, San Francisco Section.
Roy Wilkins, secretary, San Francisco Section.
L. E. Reukema, chairman, District student activities.

As nominee for Institute's vice-president for the 2-year term August 1, 1933–July 31, 1935, representing District No. 8, Prof. R. W. Sorensen (A'07, F'19) professor of electrical engineering at California Institute of Technology, Pasadena, was selected by unanimous vote.

## A Review of Foreign Broadcasting Systems

Ten years ago, 6 British radio manufacturers contributed £10,000 each to a common fund with which to commence a system of domestic broadcasting in Great Britain. They formed the British Broadcasting Company, Ltd., which, for 4 years, pioneered broadcasting. In 1926, the company obtained a royal charter and became the British Broadcasting Corporation—known familiarly as the B.B.C.—licensed by the government to transmit broadcast material of every description with only one fundamental restriction: the B.B.C. cannot accept monetary considerations from outside interests in return for broadcasting programs. In other words, it cannot transmit advertising programs for payment; its revenue is derivable solely from a license fee paid by owners of receiving apparatus.

The broadcasting system of Great Britain is almost unique. It is controlled by a board of governors appointed by the government. It operates under a license granted by the postmaster-general, who charges every set-owner 10 shillings per annum for the right to install and operate a receiving station, or in other words, a radio set. From this 10-shilling fee the post office allots a proportion (about 48 per cent) to the B.B.C. as a contribution toward the expenses of broadcasting programs and another portion goes to the national exchequer. There is nothing to insure that the B.B.C. shall receive any contribution at all from the post office license revenue and if the present 48 per cent were stopped or reduced, the B.B.C. might be forced to accept "sponsored programs."

The B.B.C. is a semi-state department as its directorial personnel is appointed by the government and its revenue granted by the postmaster-general almost ex-gratia. Also, the government of the day has first call on any air time and has more than once exercised that right. The B.B.C., as a semi-state department can be criticized in parliament. No fundamental alteration in the constitution of the B.B.C. and the present policy of British broadcasting can be effected until 1937 when the charter expires and comes up for renewal or modification.

Broadcasting is vastly different both on the continent and in the United States, the latter being entirely on a commercial basis. Canada now has decided to remodel its broadcasting system from the American method of commercialization to the British method of centralized control directed to securing highest entertainment value. Government control is also effective in Czechoslovakia, when the Prague station broadcasts some of the most popular programs. Danish broadcasting is governed by the state radio council and financed by the proceeds from license fees.

France has its own method. While there is no monopoly as there is in Great Britain, the majority of the stations are owned by the government through the ministry of posts, telegraphs, and telephones. There are 28 broadcasting stations in that country. A license fee of one franc per year is charged French citizens while foreigners have to pay 10 francs per year.

A broadcasting monopoly is enjoyed by the postal service in Germany while broadcasting is prohibited in Greece, although the government is contemplating creating a monopoly. Monopolistic control is effective also in Hungary where radio is under the control of the postal administration and about 2s. 6d. per year is charged to receivers. Broadcasting is also a monopoly in the Irish Free State and 10s. license fee, as in Great Britain, is charged. Before the end of this year a new high-powered station will be opened in Ireland, whence "sponsored programs" will be transmitted.

The broadcasting situation in Holland is peculiar and almost resolves itself into a war between the non-partisan Association of Listeners, with about 100,000 paying members, the Socialist, and the Catholic broadcasting organizations. There are 2 Dutch stations—Hilversum and Huizen—but only one station can function at a time and the time allotted to each organization is computed upon the basis of the number of members belonging to each. The authority which decides all radio matters is the Radioraad which is presided over by a high government postal official.

—Excerpts from an article appearing in *Industrial Britain* for August 1932, p. 3.

## Noble Prize Awarded to Institute Member

The Alfred Noble Prize for 1932 is to be awarded to F. M. Starr (A'30) for his paper "Equivalent Circuits—I." This paper was presented at the A.I.E.E. winter convention, New York, N. Y., January 25–29, 1932, and was published in the A.I.E.E. TRANS., v. 51, 1932, p. 287–98. An article based upon this paper was published in ELECTRICAL ENGINEERING for August 1932, p. 555–8. An item regarding Mr. Starr is given in the personal columns of this issue.

This is the second award of the Alfred Noble Prize, the 1931 award having been made to Prof. C. T. Eddy of the Michigan College of Mining and Technology, Houghton, Mich. The prize was established in 1929 and at present consists of an award of $500 from the income of the fund contributed by engineers and others in honor of Alfred Noble, past-president of the American Society of Civil Engineers and of the Western Society of Engineers, and for the purpose of perpetuating his name and achievements. Alfred Noble, one of the most prominent civil engineers active during the 50 years preceding 1914, in addition to his technical achievements was greatly interested in the younger men of the engineering profession.

The award is made to a member of any grade of either the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, The American Society of Mechanical Engineers, the American Institute of Electrical Engineers, or the Western Society of Engineers, for a technical paper of particular merit accepted by the publication committee of any of the foregoing societies for publication, in whole or in abstract, in any of their respective technical publications, provided the author, at the time the paper is accepted in practically its final form, is not over 30 years of age.

The recipient of the prize is selected by a committee of 5, consisting of one representative of each society, the award being based upon papers published by the societies within the 12 months preceding July 15 of each year. The report of the committee is made to the board of direction of the American Society of Civil Engineers at its October meeting, which was held this year at Atlantic City, N. J., October 5–8. The award will be made to Mr. Starr by a representative of the American Society of Civil Engineers at a future meeting of the A.I.E.E.

# Last Year's Unemployment Relief to Serve as a Guide for the Future

PLANS for unemployment relief during the coming winter are being made in all sections of the country and must play an important part in the activities of engineers. A review of the work accomplished in various cities during the past year may be of assistance to those groups which are making plans for the coming season, and therefore is attempted in this article. Plans which are being formulated at present by different organizations will be announced soon and will be reported in future issues of ELECTRICAL ENGINEERING.

During the past year engineers in all sections of the country have proved themselves willing and anxious to assist their fellows, with the results that much good was accomplished and distress almost entirely eliminated. The assistance given took many forms, ranging from outright gifts to temporary or more permanent loans, the securing of temporary positions, many of these in "made" work, as well as the finding for many engineers of permanent positions in industry. It is generally felt that the results of last year's efforts warrant being sustained through the coming winter. In general, the needs which are anticipated seem to be not greatly different than those which existed last winter and the maintenance of the scale of the relief given last year should be adequate through the coming year. Too much stress, however, cannot be made of the fact that concerted and active effort is necessary immediately. Some of the novelty which relief workers experienced earlier in the campaign against unemployment has doubtless worn off and those engaged in the coming campaign realize that serious effort must be made.

## INSTITUTE SECTION ACTIVITIES

Activities of the Institute providing for unemployment relief have been carried on by the Sections. Following a resolution recommending such action, adopted by the Board of Directors at a meeting held October 23, 1931, Sections of the Institute throughout the country participated in the organization of committees of engineers, usually composed of representatives of all the engineering groups in the community, and cooperating with other local civic relief organizations.

Surveys have been conducted by these Section groups to determine the need for relief and the extent of local opportunities for constructive work or employment, using the aid of engineers who are at present unemployed as far as possible. Funds for loans to deserving unemployed engineers have been collected and administered.

Many valuable data have been collected by the questionnaires which have been sent out by many of the Sections. By this means the number of unemployed has been ascertained quite accurately, together with information on the urgency of the cases, and types of positions for which the individuals are fitted. A survey of the industries in each locality has disclosed many positions which could be filled to the advantage of both employer and employee. Surveys of municipal projects which could be undertaken have been a most important phase of the work. Efforts which for some time have been carried on to reduce the number of working hours both in government bureaus and industries is producing some results, although not as extensive as was originally hoped for.

Educational activities, particularly in the metropolitan areas, have done much to maintain the morale of those unemployed and to prepare them for other positions in industry. This activity, comparatively new, has assumed different forms, but the assistance of established educational institutions usually is secured in formulating courses and securing instructors.

**Table I—Classification of Placements**

| | |
|---|---|
| On P.E.C.U. payrolls | 308 |
| Receiving other relief, such as that given by the Gibson, Bliss, and general public committees in the metropolitan district of New York | 960 |
| In permanent engineering jobs | 246 |
| Total | 1,514 |

Many of the local committees, although active, have not supplied detailed information regarding their procedures and results, and consequently a full report on these activities cannot be made to other Sections of the Institute. However, in many cases the activities of Institute members have been so closely interwoven with those of other civic groups that no separate report could be given.

## NEW YORK CITY UNEMPLOYMENT ACTIVITIES

The plan developed for unemployment relief in the metropolitan district of New York, N. Y., was carried out during the past winter with considerable success. The details of this plan were described in ELECTRICAL ENGINEERING for March 1932, p. 205–7. The organization formed "The Professional Engineers Committee on Unemployment" is known locally as the "P.E.C.U." and represents the New York Sections of the 4 national societies of civil, mining, mechanical, and electrical engineers. The first meeting of the P.E.C.U. was held October 21, 1931.

In addition to other forms of activities and assistance, the New York sections of these 4 national engineering societies made up a separate fund to take care of overhead expenses of the P.E.C.U. The Institute's New York Section more than filled its quota, and secured a margin to start the coming winter. This fund was secured by donations of $1 from members of the Section.

Up to October 11, 1932 the P.E.C.U. had a total of 2,188 active registrants among unemployed non-members and members of the 4 national societies. In addition to these active registrants, over 500 others had registered but were not regarded as active applicants for relief, as they had registered for educational courses, did not reply to letters, or had later stated that they were interested only in permanent engineering positions, not in relief. Of the 2,188 active registrants, 1,514 placements have been made. These may be divided as shown in Tables I to IV.

## TYPE OF WORK SECURED

Of the 1,514 engineers placed by the P.E.C.U., 419 were placed with the Emer-

**Table II—Division Among Society Members and Non-Members**

| Society | Registered | % of Total Registration | Placed | % of Total Placed | % of Registered Placed |
|---|---|---|---|---|---|

### Table IV—Analysis by Salary Groups

| Previous Salary | Registered | | Placed |
|---|---|---|---|
| $6,000 or better | 130 | | 106 |
| $3,600–$6,000 | 512 | | 381 |
| $2,400–$3,600 | 1,028 | | 627 |
| $2,400 and below | 496 | | 218 |
| | 2,166 | | 1,332 |
| Unaccounted for | 22 | | |
| | | Replacements | 182 |
| Totals | 2,188 | | 1,514 |

gency Work Bureau, known as the Gibson committee, mostly in city bureaus, colleges, and universities, and relief work in this district. Men were employed in city departments for surveying, drafting, making mechanical plans and specifications for hospitals, for traffic surveys, as playground and gymnasium instructors, plan examiners for municipal buildings, and truant officers; as assistant professors, draftsmen, general office workers, stock men and laborers in colleges and universities; and for the collection of city relief funds and the carrying on of home relief investigations for other relief organizations.

The City Work and Relief Administration, known as the Bliss committee, took 392 of the men as key men in home organizations, timekeepers, checkers, payroll men, pay masters, and field men engaged by the heads of various city departments, mostly in construction and maintenance work.

In other organizations, 31 were engaged in a topographical survey, 44 for surveying in an outlying county, 64 by the Westchester County Park Commission, mostly for general laboring work, and 10 others in 3 smaller units.

The P.E.C.U. itself employed 60 salary workers on the home office staff for interviewing, registering, classifications, placement, payroll, consultation bureaus, investigations, and soliciting funds. A total of 248 others are paid directly by the P.E.C.U., but are assisting other organizations in a great variety of work.

Permanent engineering positions have been secured for 246 men. Some of these are not strictly engineering activities but may be classed as permanent positions.

## SOURCES OF FUNDS

The amount raised in cash and pledges, the number of contributors, and average amount individually contributed by the membership of the 4 national societies in the metropolitan district of New York are shown in Table V. The canvassing for this money was done in 3 ways: by letters of appeal; by unemployed engineers as canvassers or solicitors, they being paid the relief wage; and by voluntary committees of members of the societies doing personal canvassing. The letters of appeal were 4 in number. The first went to the 13,000 members of the 4 national societies in the metropolitan district of New York. The second, third, and fourth were sent to those who had not replied to the preceding letters, it being necessary to mail but 5,400 copies of the last letter. The engineers were divided into 2 classes: (1) a special group supposed to contain the more affluent members of the profession, to the number of 571; and (2) the remainder of the members. Contributors on the special list to the number of 183 gave $30,526.60, or an average sum of $166.80 each.

Of the total of $109,723.96, about $20,000 was originally in the form of subscriptions or pledge cards, the donor electing to contribute on a monthly or weekly basis over varying periods of time, some as long as 5 months. Experience indicates that only about $1,000, or roughly, 5 per cent of the total number of pledges are in default. In nearly every such case the pledger has lost his job since undertaking his obligation. The total sums obtained to May 15, 1932, are shown in Table VI. The first figure, $107,841.09, shown for that date corresponds to the figure of $109,723.96 shown in other tables as of October 11, 1932.

### Table V—Analysis of Contributions to Oct. 11, 1932

| | No. of Contributors | % of Total | % of Membership in Territory | Total Contributions | % of Total Contributions | Avg. |
|---|---|---|---|---|---|---|
| Civil | 787 | 22.46 | 22.5 | $ 34,547.38 | 31.4 | $43.90 |
| Electrical | 1,134 | 32.40 | 30.4 | 22,502.62 | 20.5 | 19.84 |
| Mechanical | 1,115 | 31.83 | 38.3 | 25,282.96 | 23 | 22.67 |
| Mining | 265 | 7.56 | 8.8 | 12,222.47 | 11.2 | 46.12 |

## TYPES OF RELIEF PROVIDED

The average relief afforded the individual unemployed engineer through the P.E.C.U. up to May 15, 1932, has been $19.05 per week; this sum has varied somewhat depending upon where the relief was obtained, as shown in Table VII. At that date there had been 73 loans granted in amounts in excess of $15, totaling $3,355, and averaging $45.18 per man. There had been 60 emergency loans granted in amounts less than $15, totaling $248 and averaging $4.13 per man.

These loans were on demand notes without interest. The expectation is that ultimately a considerable percentage of the borrowers will repay them. The funds so collected will be reserved for possible future use.

The relatively small number of loans made and the meager sums of money required surprised those active in the P.E.C.U. Apparently engineers (especially our members) are extremely loath to apply for loans. They much prefer wages from made work or even direct relief from city bureaus. Also, a loan meets only the momentary emergency.

The P.E.C.U. has been very active in persuading the gas and electric light companies to forebear enforcing routine orders to discontinue their services to destitute engineers. In some instances it has been possible to persuade holders of mortgages to be more lenient in the terms on which they extended or renewed them. Occasionally money has been loaned to pay interest on mortgages.

A legal aid department has been established, whose function has been to give free legal advice to registered unemployed whose circumstances were such that they required such advice. Similarly, an agency has been set up to assist registered unemployed who had developed inventions or processes possibly warranting patents. Assistance also has been given registered men in preparing letters outlining their past experience in a way to interest the prospective employer. This has been supplemented with a mimeographing service to produce multiple copies of such letters.

As regards clothing, the McGraw-Hill Company donated floor space and 2 unemployed engineers were set to work to operate a clothing bureau. On May 14, 1932, 203 men, 61 women, and 58 children had been provided with clothing, contributed largely through the efforts of the Engineering Woman's Club of New York. This clothing has been a godsend to many unemployed men, who, if they had not had

### Table VI—Total Sums Obtained to May 15, 1932

| | |
|---|---|
| Cash and pledges | $107,841.09 |
| Second-hand clothing, est. value | 4,500.00 |
| Unexpended balance of state and federal contributions for U.S. geological survey | 11,330.00 |
| Raised separately for administrative purposes to cover such items as postage and telephones | 5,247.00 |
| From President Hoover and the Engineers' Club of N. Y. for engineers outside the metropolitan district of N. Y. | 5,700.00 |
| Wages paid by semi-public bodies to P.E.C.U. engineers at the instigation of the P.E.C.U | 307,119.00 |
| Total | $441,737.09 |

### Table VII—Average Relief Afforded

| | |
|---|---|
| For those paid direct through P.E.C.U.'s payroll | $18.82 |
| For those who obtained relief through the Gibson, Bliss, and other relief committees | 21.50 |
| For those who got engineering jobs through P.E.C.U. and other sources | 32.50 |

the clothing, in many cases could not have taken the positions which were found for them. The Engineering Woman's Club not only collected and distributed clothing but also initiated and managed a charity bridge party. Some 700 tickets were sold at $2 apiece, the result being that a net contribution of $1,160 was made to the funds of the P.E.C.U.

Another successful activity was that of certifying unemployed engineers to Columbia University so that they could attend classes without academic credit and without expense. A total of 138 men made 564 registrations in 163 different courses for the winter and spring terms.

Another important committee which was recently established is known as the committee on industrial opportunities. This committee endeavors to place engineers outside the profession. It has prepared a list of some 800 industrial concerns which in its judgment could use engineers for cost studies and in other ways where their technical training and mathematical ability would make them more useful than the ordinary layman. This committee continued its work all summer, and has been reinforced by 2 other groups who solicit positions of a permanent nature. Members will greatly assist the P.E.C.U. if they will kindly inform the committee of any positions they may know of that might be filled by a man with engineering training.

Another committee, known as the committee on construction legislation, has been active in Washington and Albany in endeavoring to persuade congressmen and other legislators that the cutting out of construction enterprises from federal, state, and municipal budgets is fallacious economy, results in great increase in unemployment, and is particularly distressing to engineers.

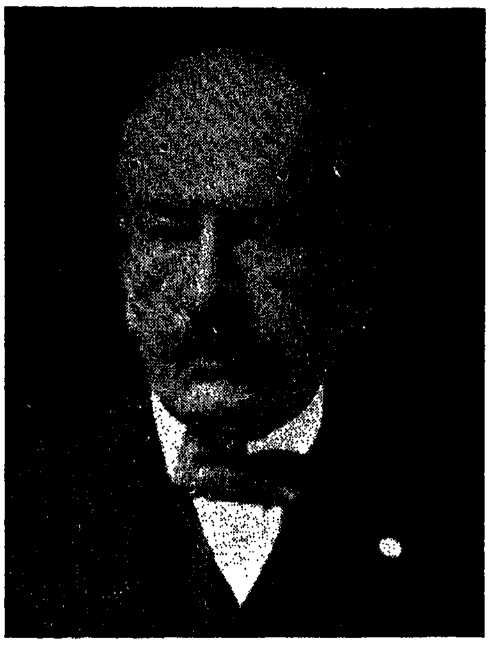
Reviewing the activities of the past winter, the P.E.C.U. feels that its greatest accomplishment has been to convince the semi-public relief agencies of the desirability, from their point of view, of using unemployed engineers in supervising capacities or as key men in directing the 35,000 or 40,000 individuals to whom these agencies have had to give unemployed relief in the form of made work or as direct relief. Extreme care was taken in certifying registrants to these public bodies, to make certain that the candidates sent were qualified for the job in question.

A large part of the work of the registration committee has been to classify all registrants as to their prior experience and their fitness for different types of work. Care along these lines in the early stages of the activities has been rewarded many times over.

### Summer Activities Curtailed

Registration of unemployed engineers ceased on April 9, 1932, as it was felt necessary to curtail relief work during the summer months and conserve funds for the coming winter. A small staff was maintained by the P.E.C.U. during the summer months, most of the attention being given to seeking permanent positions for the men, although the most destitute cases were carried throughout the summer. Plans for the coming winter are now being made, and will be announced in future issues of Electrical Engineering.

## In Memorium



C. O. MAILLOUX

On the fourth day of October 1932, the American Institute of Electrical Engineers suffered a great loss in the passing on of one of its most revered members, Dr. C. O. Mailloux.

Throughout Dr. Mailloux's career the cause of the Institute has been one of his foremost interests. From the early days of his activity in the organization meeting of May 1884, down through his many years of active service on the standards committee, the Edison Medal committee, the John Fritz Medal board of award, through his work on the United States national committee of the International Electrotechnical Commission, and the presidency of the Commission itself; his years as a director and vice-president of the A.I.E.E., his term as President in 1913–1914, Dr. Mailloux stood and fought for the ideals of the Institute, the maintenance of its high professional standing. Therefore be it

RESOLVED: That the Board of Directors at the meeting of October 12, 1932, record its deep appreciation of these many years of faithful, unselfish work carried on in behalf of the Institute by Dr. Mailloux, its realization of the loss which the Institute has suffered, and its sincerest sympathy to those from whose association he has been taken. And be it further

RESOLVED that this minute be spread on the offical records of the American Institute of Electrical Engineers and that copies be sent to his relatives.

—A.I.E.E. Board of Directors, Oct. 12, 1932

### Relief Program in Boston, Mass.

Following independent surveys initiated by the Boston Society of Civil Engineers and the Boston Society of Architects, it was decided toward the end of 1931 that the needs could be met best by cooperation between the professions of engineering and architecture. The Engineering Societies of Boston, composed of 12 member societies, immediately endorsed this plan and appointed an executive committee as well as the following 5 working subcommittees: finance, registration, administration, development, and publicity. As of June 16, 1932, a total of 198 engineers has been given employment, and 121 architects have been placed. A total of 865 engineers and 212 architects had registered on that date as being in search of employment.

The Emergency Planning and Research Bureau, Inc., was formed having 2 divisions, an engineers' division and an architects' division. Each of these divisions administers its own funds, selects the type of work which the men are to do, and keeps its own accounts, all these activities being coordinated through the board of directors of the bureau. The finance committee raises funds from employed members of the profession, these generally contributing one day's pay per month for a period of 20 weeks beginning January 24, 1932. Large organizations are covered by a team captain, and the Society members and other engineers are appealed to by letter. In this manner $79,004.62 was pledged by 2,429 individuals. On June 16, 1932, the period of the pledges not yet being up, $62,024.02 had been received.

Contributions received by the committee were credited to the amount received by the United Boston Unemployment Relief Committee, although the latter had nothing to do with the handling of funds collected by the engineers' and architects' bureau. Contributors to either fund were given the same card and button to avoid the annoyance of any one's being requested to donate to both organizations.

### Registration of Applicants

Each applicant registering with the bureau is asked for his exact financial condition in addition to the standard information on education and experience. If his financial condition is critical, the social welfare organization is asked to make a report on the case. This is reviewed by the registration committee, a member of which personally interviews each man. When the committee is satisfied of the need, the applicant is referred to the chairman of the administration committee, who places his name upon the payroll. He is then assigned to work in the drafting room of the bureau.

In determining the work which these men shall do, the development committee has followed 3 general principles:

1. The work shall not conflict with that of any employed engineer and it shall not take work away from any engineer.
2. The work must be of such a nature as to come within the classification of engineering.
3. Not only will the man himself be benefited, but there shall be a possibility that the project will open more work for the engineering profession or that it will be demonstrated that an engineer is the logical man for that type of work.

The projects are of a varied nature, and include:

1. Work for the City of Boston with the architects' division on mapping of city owned property and

blocking of the 1930 census, housing studies, depreciation studies of downtown business sections, and correction of maps for street changes for the planning board.

2. Work in connection with state departments for which there have been no funds available, such as fire protection studies at institutions, surveys in connection with public reservations, smoke investigations, traffic counts, plotting statistical data, surveys of state institutions, gathering of existing data on refrigerating and heating plants at state institutions.

3. Compilation of existing facts relating to New England that can be used for a regional study of this area, such as trends of population, transportation, local government finance, present status of zoning, and use of land in each county.

4. Library research work for committees of various engineering societies.

### EMPLOYMENT BUREAU

An employment service has been set up within the bureau and operated under state and city laws. No charge is made for services. Two employees of the bureau devote full time to this work, making contacts with organizations which ordinarily do not employ engineers, to "sell" the idea of using engineers. Previous to June 16, 1932, a total of 48 men had been placed in positions having an estimated total income of $10,640. In addition, 74 registered men have gone into work for which there is no income record, the yearly income of all men registered and now employed elsewhere being estimated at $210,000.

The executive director of the engineering division devotes his entire time and is responsible for the work done by the bureau, including the preparation of a weekly report. Office space and equipment have been donated by various organizations. The stationers and makers of blueprints furnish material at a substantial discount. The men work 7 hours per day, 5 days per week, at the rate of $3 per day.

The men receiving assistance are all married, with one or more dependents, the average being 3. For the 130 men on the payroll, the weekly disbursements average $1,600. The payroll expenditure to June 16, 1932 has amounted to $35,977.50, which is 98 per cent of the total expenditures of the bureau. Of the 865 engineers who have registered, 621 or 71.8 per cent, are non-members of any engineering society. The age analysis of registrants is shown in Table VIII.

**Table VIII—Applications in Age Groups**

| Ages | No. | Ages | No. | Ages | No. |
|---|---|---|---|---|---|
| 18–20.... | 6 | 31–35.... | 111 | 46–50.... | 32 |
| 21–25.... | 116 | 36–40.... | 108 | 51–60.... | 27 |
| 26–30.... | 162 | 41–45.... | 70 | 61–67.... | 6 |

**Table IX—Subscriptions to Oregon Technical Council Fund**

| Society | Total Subscriptions Paid In—Sept. 3, 1932 |
|---|---|
| Am. Inst. Mining & Metal. Engrs. | $263.00 |
| Am. Soc. Mech. Engrs. | 259.00 |
| Am. Inst. Elec. Engrs. | 774.00 |
| Prof. Engrs. of Ore. | 280.00 |
| Am. Soc. Civil Engrs. | 579.50 |
| U.S. Army Engrs. Unemployment Fund | 462.11 |
| Federal Employees Unemployment Fund | 439.53 |
| Miscellaneous | 5.00 |
| Total | $2,762.14 |

### RESULTS

Favorable publicity has been given the bureau by newspapers, speakers, and by exhibits at conventions and in clubs. The publicity director of one of the public utilities has assisted in this work. It is felt that the development of the welfare plan has resulted in the following benefits:

1. A better understanding among the individual engineering societies comprising the Engineering Societies of Boston.

2. A better understanding of the engineering profession by the general public.

3. The practical example of a well-planned and smoothly operating welfare organization, which has been cited as a model for other groups attempting to solve the relief problem within their ranks.

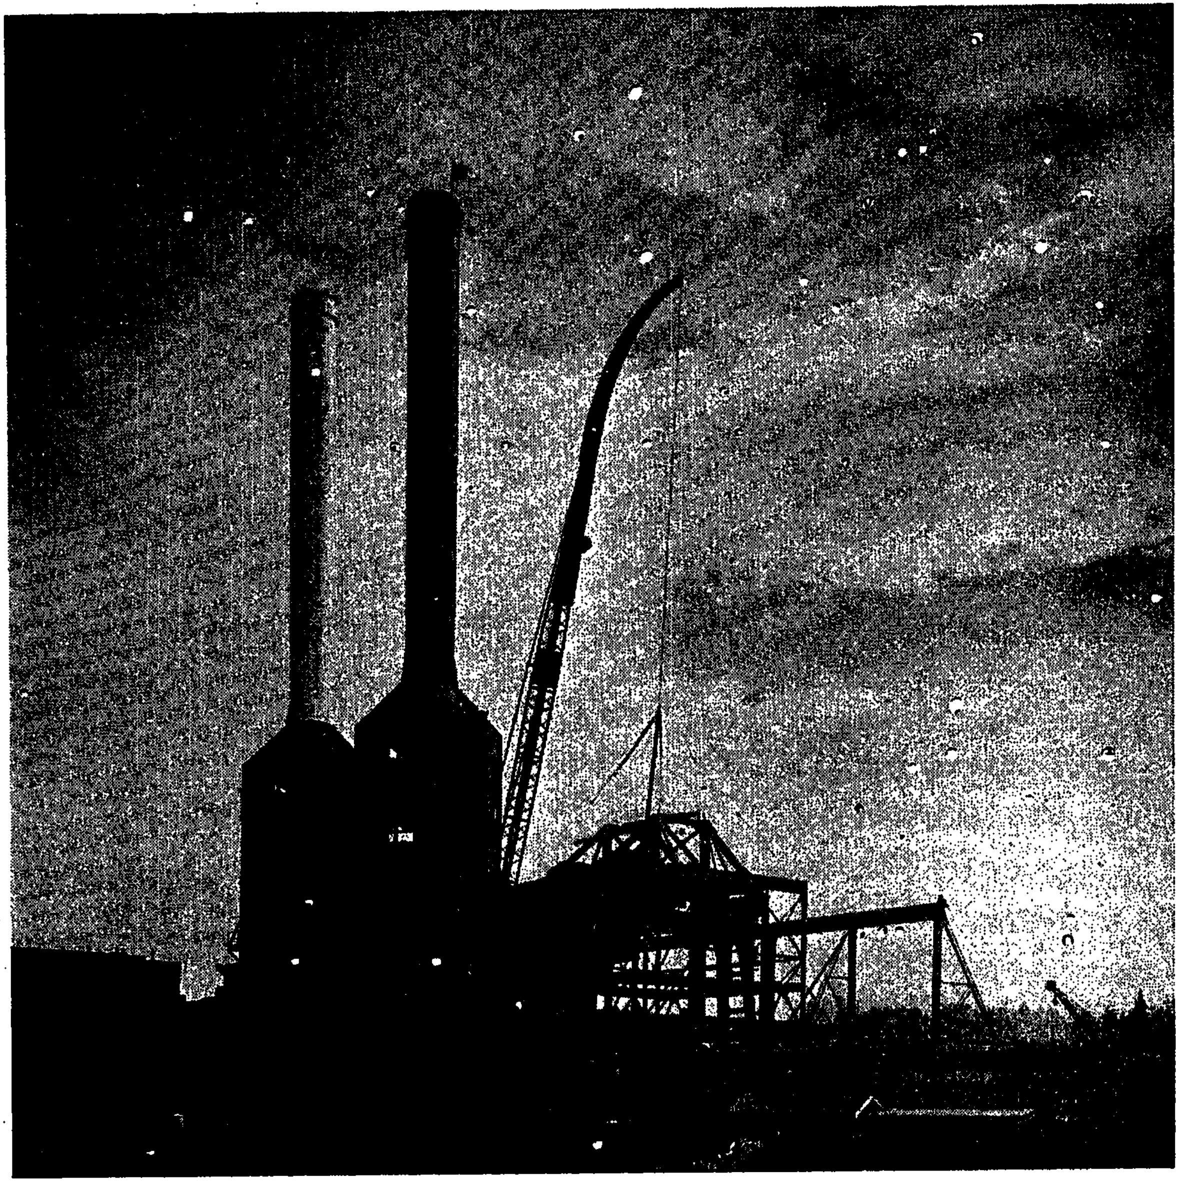
4. Improved morale of the unemployed engineer, who has been made to feel that he is producing work of value along the lines in which he has been trained, instead of feeling that he is a recipient of charity, giving nothing in return.

5. A closer relationship and a better understanding between the architects and engineers.

### ACTIVITIES IN SOME OTHER CITIES

Lack of space combined with incomplete reports unfortunately do not permit a comprehensive review of the unemployment work which has been accomplished throughout the country. Much of this work has been of tremendous value assuring employment for needy cases and in sustaining morale. The San Francisco Section of the Institute accumulated a sizable fund which

## New Mercury Vapor Turbine to Be Largest in Size



CONSTRUCTION of an unusual power plant to cost some $4,000,000 is being undertaken at Schenectady, N. Y., by the General Electric Company. Perhaps the most unusual feature is that a mercury boiler and turbine will be used, although no little interest is attached to the fact that it is to be the first outdoor steam-electric generating plant. The mercury turbine is rated 20,000 kw, and the station 25,000 kw, as there is also a 5,000-kw non-condensing steam unit. By-product steam will be secured from the mercury condenser; a steam boiler also will be included in the outdoor station. The electric output of the plant will be supplied to the commercial system of the New York Power and Light Corporation, while the steam output will be used in the General Electric works. The mercury vapor will be at a temperature of 958 deg F and 125 lb gage; the steam will be at 760 deg F and 410 lb initial pressure. It is contemplated that the plant will be ready for operation in the spring of 1933.

was used primarily in the form of loans to members or past members of this Section. An interesting procedure was followed by the California division of highways which maintains 2 camps where men are given the privilege of doing part time work on highway improvements in exchange for board and room. The men sent to these camps were distinctly above the average type of laborer in such camps, and were mostly young men. About 500 were cared for by this method.

An organization of unemployed engineers of Philadelphia, Pa., was formed for the purpose of keeping up the morale of their fellow engineers, and assisting employers in securing competent technical help. Approximately 1,000 men have been registered with this group, "The Philadelphia Technical Service Committee," and positions are being found in all branches of industry. (See ELECTRICAL ENGINEERING for July 1932, p. 526.)

As of May 28, 1932, the Engineers' Relief Committee of Pittsburgh, Pa., has collected $6,148.86, unpaid subscriptions amounting to $2,167.16. This has been expended as follows: $2,403.75 for 174 loans to be repaid by 55 individuals, $3,215.76 covering 230 contributions to 46 individuals, $146.10 for operating expenses, leaving a cash balance of $383.25. A total of 209 cases also had been handled at that time, 55 men having been placed in employment and 69 men paid from the committee's funds. Only the most destitute were assisted.

The Oregon Technical Council, Portland, has been disbursing funds for engineers' relief since March 10, 1932. A total of $1,750 has been loaned to 21 applicants. These loans usually run from $5 to $60, no applicant having received over $200. $2,762.14 has been paid by 121 subscribers, about $800 still remaining in the bank on September 3. The sources of the fund classified by societies are shown in Table IX. Plans for the coming year contemplate raising a larger amount from a much larger number of individuals, thus relieving the burden on those subscribing. These subscriptions are not donations, but are loans which will be returned as the loan notes are repaid.

The plan of the Rochester, N. Y., engineering groups last winter was to pool their interest with that of the American Engineering Council's committee on unemployment of western New York, which was organized to assist in promoting work which would bring more employment to engineers in this community. An emergency relief campaign also was organized in Rochester in which the citizens agreed to spend $6,000,000.00 during 3 months for improvements to their homes, factories, or offices. Of particular interest in this section is the "Rochester plan" which was organized by some 15 Rochester industries to assist in relieving unemployment in the State. This plan, quite well known throughout the country, does not become operative until 1933, but should be an important step in curbing future depressions.

# Letters to the Editor

CONTRIBUTIONS to these columns are invited from Institute members and subscribers. They should be concise and may deal with technical papers, articles published in previous issues, or other subjects of some general interest and professional importance. ELECTRICAL ENGINEERING will endeavor to publish as many letters as possible, but of necessity reserves the right to publish them in whole or in part, or to reject them entirely. STATEMENTS in these letters are expressly understood to be made by the writers; publication here in no wise constitutes endorsement or recognition by the American Institute of Electrical Engineers.

## Consumption, Production, Distribution

*To the Editor:*

The report on the present economic situation rendered by the American Engineering Council (see ELECTRICAL ENGINEERING for June 1932, p. 373–7) seems to me so far beside the facts, so full of obvious inconsistencies and direct contradictions, that, rather than give time to a discussion of the "Report" itself, I shall present hereafter certain specific conclusions I have reached as to the past performance of the existing economic system. Only in this way, I think, is it reasonably probable that any proper deductions as to cause and effect can be drawn.

The conclusions presented are drawn from a very extensive research and energy survey of North America now being conducted by "Technocracy" in the department of industrial engineering in Columbia University. The conclusions are reached through an application to the data of the theory of energy determinants.

The enormous quantity of associated data covering a large number of products over long periods of time and made available through this research proved to be the only source extant from which any direct conclusions could be drawn. Certainly no such data are to be found in any existing treatise or work on economics, nor do the publications of the several industries, our financial institutions, or of the Government, present the required information in logically assimilable form.

A considerable reading in the so-called science of economics has led me to the inevitable conclusion set forth by Veblen, that the foundation of this science rests upon the economic preconceptions of the 18th century, and that it merely attempts to describe our modern economy in these terms. Certainly no "law" of this science has been based upon thoroughgoing analysis of performance in fixed measured units. The "law of supply and demand" is an instance. It appears to me that economics was still in the state of physical science before the birth of Galileo. Nothing has yet been written that attempts to aline the performance of money and price with the performance of the production-distribution-consumption system in terms of a common unit of measure.

Physical energy is fundamental in modern civilization. If its flow ceased (no coal, no oil, no water power, no electric power) our civilization would cease and we would starve to death in 20 days or thereabouts.

The change from man-power at 0.1 hp per unit to mechanical power of unlimited hp per unit began in 1840, and since then has increased at a rate approximating the 8th power of the time. Double the time and our civilization has used $2^8 = 256$ times the power. Between 1830 and 1930 the amount of power used in the United States increased 360 times. At the present time we, on the average, use 150,000 kg-cal of energy per capita per day. Of this only 7 per cent is involved in sustenance (food). The remaining 93 per cent is used in making, distributing, and operating things not sustenance, such as automobiles, railroads, all applications of electric light and power, buildings, and clothing.

Put this measure on any living scale in any part of the world at any time, and much may be learned about the economy of that place and time. Previous to 1840 in all known civilizations, and in China today, the rate of energy dissipation did, and does not, exceed 2,000 kg-cal per capita per day. The implication as to social change and all its concomitants is obvious and significant. Mark you, this change from all of the past has taken place in not quite a century! Observe that, in spite of our vaulting assumptions, on this scale, our living "standard" in relation to our energy reserves is the lowest of any other people in the world!

At this present rate of consumption of energy all our available energy resources will have been used in a century (approximately). If the rate continues to increase as the 8th power of the time, then in 50 years from now, or by 1980, the rate of consumption of energy per capita will be 6,760,000 kg-cal per day. In such an impossible case our entire energy reserves of coal and oil would be used up at that time and all available water power would be entirely insufficient.

It matters not a rap what men think, wish, or desire. We are face to face with a law of nature. The law of conservation of energy has a perfectly definite social implication, and, as a corollary to that, a perfectly definite political implication! It follows that Malthius' law requires restatement in terms of energy.

The average production of all goods has increased since 1840 as the 3rd power (cube) of the time. Since 1890 production as a whole in 1928 had tripled. Some products have increased at much greater rates. Steel production has increased as the 6th power of the time. The continuation of such rates of growth is physically impossible. If the maximum rate of growth in coal production had maintained for 50 years, it would require that the whole earth be a solid ball of coal!

Meanwhile the man-hours used per unit of production has decreased at similar rates. In steel, the rate of decrease has been as the inverse 4th power of the time, in automobiles even greater. In pig-iron production one man-hour does today what 650 man-hours accomplished 100 years ago. In agriculture it requires but 1/3,000 of the man-hours per unit of product required in 1840. In incandescent lamp manufacture one man-hour accomplishes as much as 9,000 man-hours accomplished only so short a time past as 1914! One can go on indefinitely marshaling such facts. The ratio for the whole since 1840 is not far from 1/3,000.

The rate of decrease in man-hours as a

whole is greater than the rate of increase in production, and since 1918 the rate of decrease in man-hours has been approximately the same as the rate of increase in power efficiency of production. We are now substituting kilowatthours for man-hours on a parity basis—1,500,000 ft-lbs per 8 hours = 1 man.

If the rate of decrease in man-hours maintains for 50 years, there will be 20,000,000 unemployed in this country. At the peak of production in 1928 there were nearly 3,000,000 unemployed workers—an amazing fact when you first run into it. If the whole production plant were put to work at full capacity today, there would be about 6,000,000 unemployed workers.

Observe that, in spite of our technical supremacy, the energy efficiency of our civilization grows less at an accelerated rate! Deterioration of quality under the stimulus of competitive "cost" and its concomitant hastened obsolescence through use—in other words, waste—indicates one reason for the wide departure between the rates of increase in energy flow and increase in production, even after deducting the rate of substitution of kilowatthours for man-hours.

The above 3 fundamental facts, (a) the important place of physical energy in our civilization, (b) the growth rates of production which cannot maintain, and (c) the fact that the decrement in man-hours exceeds the growth of production, form the only proper basis for discussion of the present situation or future possibilities. The facts given are not wild guesses. They are a few resulting from careful analysis of much available data that has been checked several ways, and submitted to criticism.

Now to another matter. The industrial debt of this country—bonds, mortgages, bank loans, and all other interest-bearing amortized securities—totals approximately 218 billions. Taxes and obsolesence included, the fixed charges on this debt is 34 billions a year—practically half the national income of 1928! Since 1840 this debt has increased as the 4th power of the time. In other words, we owed in total 16 times as much in 1930 as we owed in 1895. The Government had in issue (June 30, 1931) about 6 billion certificates of debt in the form of demand notes called paper money. Add this to the 218 billions to get a grand total of 224 billions of debt based on 5 billions of gold, or roughly speaking, our money assets have to our liabilities the ratio of 1/50 or 2 cents on the dollar! The war debts are mere pocket change. What would be said of a manufacturing concern in such a financial position? What action on the part of the creditors would naturally follow?

Note that population has been increasing as the square of the time. Therefore the ratio of debt to population increases as $t^4/t^2 = t^2$, or as the square of the time. In 1930 each one of us on the average owed 4 times as much as we owned in 1895. If you think this cannot be correct, look up the data yourself.

Note also that while the debt increases as the 4th power of the time, production increases as the 3rd power of the time. It follows that the debt, which must be supported by the sale of produced goods, increases faster than the production of these goods. In other words, the goods are "put in hock" faster than they can be produced! How long, and by what kind of financial legerdemain, can such a proceeding be maintained?

Now in the light of such facts, consider the economic and financial promulgations issuing from the Hague, from Geneva, from Lausanne, and from Washington! Finally, examine the "reports" on the economic situation produced by American Engineering Council!

Indeed, it is true that "our bankers are debt merchants and economics has become the pathology of debt." Price and production have little relationship now, and ere long will have none. The obvious conclusion is that a production-distribution system, energy operated, cannot be controlled by price, and it is footless to try. Certainly our experience of the past century should show us how footless the attempt has been.

The machine is an agent of liberation. Each of our 35,000,000 workers now uses 3,000 energetic slaves in the form of 300 mechanical hp, each horsepower being the equivalent in work done to 10 human slaves. The machine as a whole actually requires but 2 (not 4) 8-hour days per week from each worker. Why should he do more when, as Russell says, "the morality of work is the morality of slaves."

Obviously each worker must have adequate purchasing power, even if he works but 660 hours or less a year. Well, why not give it to him. But if the facts set down above are fairly correct it is quite evident this purchasing power cannot be in terms of "price." The ingrained concept of price stands in the way of a clear comprehension of the economics of an energy system, quite as the ingrained Euclidian concept of the straight line inhibits a clear comprehension of a non-Euclidian space. Evidently the unit of labor or work—the man-hour—is not the proper measure of economic values for we are doing away with the man-hour.

Well, what is the answer? Certainly it is not contained in the report of the Engineering Council for one!

Very truly yours,
Bassett Jones (F'30)
(101 Park Ave.,
New York, N. Y.)

---

Author's Note: The time rates given in the above are illustrative. The actual functions fitting the data are not simple functions of the time, but do not involve higher powers of the time than those given. Thus, I have expressed population growth as the square of the time $t^2$. That is sufficiently accurate for the present purpose. The actual population growth function for the United States is given by Pritchett, $p = 9{,}064{,}900 - 6281430t + 842377t^2 + 19{,}829{,}500 \log t$. For production of goods, the functions are oscillating, the power of the time given being the highest power in the equation of the axis of oscillation.

## European Broadcasting Stations

*To the Editor:*

In connection with the short notice on "European Broadcasting Stations," appearing in Electrical Engineering for September 1932, p. 666, it may interest your readers to get a few data about the equipment used to an increasing degree in European broadcasting stations.

Late in 1928 the Marconi Company in London, England, decided to install for the new Chelmsford station a high-voltage mercury arc rectifier for feeding the amplifiers, for which purposes otherwise thermionic valve rectifiers had been used, and which give satisfactory service but unfortunately have only a very limited life, thus enormously increasing the operating costs of such stations. With a mercury arc rectifier no such difficulty could be expected and in fact the equipment in Chelmsford operated with entire satisfaction since its first starting to operate in September 1929. This rectifier was designed for an output of 400 kw at d-c voltages of 9,000, 10,000, and 12,000 volts.

Based on these favorable results, the Marconi Company has later installed a number of similar rectifiers in the stations built for Warsaw, Poland (1,000 kw, 15,000 volts direct current), Muenster, Switzerland (270 kw, 12,000 volts) and Athlone, Ireland (460 kw, 13,000 volts), this latter station having first been opened for broadcasting the features of the Eucharistic Congress held in Dublin in June 1932. The German post administration followed this example and so far equipped 5 stations with high voltage rectifiers ranging from 360 to 1,170 kw and 12,000 to 13,000 volts direct current. Other equipments of this nature will soon be put into operation in Torino, Italy, and some other European stations.

This development, accomplished in the short period of 4 years, shows that mercury arc rectifiers as designed for this special purpose are bound to replace successfully thermionic valve rectifiers with their limited life period, and shows that they have already secured a firm place in modern radio station equipment.

Very truly yours,
Paul R. Sidler (A'31)
(New York Representative, 19 Rector St., New York, N. Y., of Brown, Boveri and Co., Baden, Switzerland)

## Engineering and Human Happiness

*To the Editor:*

Many of your contributors and correspondents on the subject "Engineering and Human Happiness" recognize in some measure that "man's life consisteth not in the abundance of the things which he possesseth," and that the fundamental condition for individual happiness is an inward or spiritual state characterized by peace of mind and love for one's fellow men. As to what power can create that fundamental condition, no answer is nearer the truth than that of Doctor Pupin in your March issue. (See Electrical Engineering, March 1932, p. 156–7.)

. . . Given a proper spiritual foundation, true happiness can exist with the minimum of physical necessities or even without them. Engineering as a factor in human happiness seems therefore to be mainly dependent upon the spiritual state of the individual and of society as a whole. Only when man is inwardly prepared for a right use of the gifts of science will the world be safe for engineering progress.

Very truly yours,
C. Kent Duff (A'28)
(University of Toronto,
Toronto, Ont., Canada)

## "Class O" Insulating Materials

*To the Editor:*

The A.I.E.E. standards committee in 1922 provided an additional class of insulating material, namely, "Class O—Cotton, silk, paper, and similar materials when neither impregnated nor immersed in oil."

The committee, possibly influenced by the business depression of 1921, acted in response to a demand for cheaper electrical apparatus. We are again in the midst of a far more serious business depression, and we now have abundant time to contemplate past history. Can we say that we were justified in abandoning the fundamental principles upon which dependable insulating materials are based? Does it pay to ignore the superior qualities of impregnated absorbent materials saturated with a suitable substance that replaces the residual moisture and air between its fibers—entirely covers its fibers and renders them adherent to each other and to the conductors—a substance that will not flow or evaporate during the operating service of the machines regardless of overloads or prolonged action of heat?

Why not repeal the 1922 amendment ("Class O" insulation) and while we are about it, omit the words "organic" and "inorganic" wherever mentioned, as we depend upon the useful blending together of all components to make one solid homogeneous winding structure.

In conclusion, may I say that enameled wire is in a class by itself, the most economical wire to make and to use. We don't have to impregnate the enamel coverings, and we could not if we would. We have now available ready-made, solventless, dry, and transparent varnish films (cellulose acetate films) to use as layer insulation for enameled wires; a combination that effectively eliminates varnish tanks and vacuum impregnators in magnet coil production thereby offering another argument for the elimination of "Class O" insulating materials from the A.I.E.E. standards.

Very truly yours,
H. W. Turner (A'03)
18 Troy Place, Schenectady, N. Y.)

## Engineering Foundation

### Selecting an Engineering Career

"Engineering: A Career—A Culture" is the title of a pamphlet having as its aim the assisting of young men, their parents, and teachers in high schools and preparatory schools, to answer the all-important question: Should the vocation of engineering be selected as an individual's career? Reliable information for answering this question is needed; romantic stories or enticing propaganda will not do.

The information presented in this pamphlet has been compiled by the educational research committee of the Engineering Foundation, in cooperation with the societies which its members individually represent, namely: American Society of Civil Engineers, American Institute of Mining and Metallurgical Engineers, The American Society of Mechanical Engineers, American Institute of Electrical Engineers, American Institute of Chemical Engineers, and the Society for the Promotion of Engineering Education.

Following a general chapter upon engineering requirements and opportunities, chapters are devoted to the specific branches of engineering, namely: civil, mining, metallurgical, mechanical, electrical, and chemical engineering. Chapters also are included upon the preparation for engineering, and another upon the earnings of engineers. The purpose in preparing this pamphlet has been to provide as helpful vocational guidance as practicable for engineering as a whole and not for any particular group.

In the pages of this pamphlet much is told about what engineers do, and what qualities of mind and character a youth should have to become an engineer. There is information upon the schooling that the boy should have, and upon the engineering colleges; also upon the training after college is ended and professional work is started. Some idea of the nature of the pamphlet may be gained from the following excerpts taken from the chapter on electrical engineering:

"Electrical engineers must possess mathematical abilities even greater than those necessary to other engineers, for the thing with which they deal, electricity, is energy without material embodiment, and it can be treated only as a mathematical formula. Elsewhere we have pointed out the qualities of imagination required of civil, mechanical, and chemical engineers, who deal primarily with material forces and their relations. The electrical engineer's mathematical analysis of energy and of its applications leads him into a realm of almost metaphysical speculation. . . . Multiplex telephone and telegraph systems for carrying numerous messages simultaneously over the same wires, long distance cables where hundreds of circuits within a single sheath must be prevented from interfering with one another, and the distance effect from the extremely high tension power lines which cover the country, all present problems solved only after the most exacting mathematical analysis. . . .

"Within the corporations of this (electrical) industry most electrical engineers find their careers. From the very nature of the business, large groups have become the rule. Telephone, telegraph, radio, and power transmission imply the connection of many points into systems with interests and administration in common. Growth, too, has been so closely dependent on continued active research that the economy of cooperation in this activity also has aided in the formation of large corporations."

Following also is an excerpt from the chapter on preparation for engineering:

"Engineering is essentially a scientific pursuit founded upon mathematics and natural sciences. . . . You should be prepared to analyze ideas by the logical reasoning of science and with the accuracy of mathematics. . . . The surest indication of possession of the requisite mental ability is your demonstration of it in school. If you have been consistently in the upper half of your classes, or preferable in the upper third, it is probably that you do. . . . You should clearly differentiate between the man who builds things with his own hands (a mechanic) and the professional engineer who plans the things the mechanic builds. The engineer should cultivate his capacity to visualize the intended result of his plan, to see with his mind's eye the things he plans in 3 dimensions as if they were already built."

The pamphlet will be revised as frequently as found desirable and made available to persons in all parts of the country year after year. It is being made available through the local sections of the national engineering societies, the colleges and their alumni organizations, and the Society for the Promotion of Engineering Education. Copies can be obtained also from The Engineering Foundation at 29 West 39th St., New York, N. Y. In lots of 50 or multiples of 50, the price is $10 per 100 copies. For single copies and for lots less than 50, the price is 15 cents per copy. Orders may be sent at any time; 10 per cent discount is allowed for quantity orders with cash before December 31, 1932. Remittances should be made payable to The Engineering Foundation.

## Standards

### Revision of A.I.E.E. Standard No. 4

The standard for "Measurement of Test Voltages in Dielectric Tests," No. 4 in the A.I.E.E. series, has been revised through action of the standards committee on October 11, which action was confirmed by the Institute's board of directors October 12, 1932. The revision concerns paragraph 4–102, the first 6 lines of that paragraph to be revised to read:

"*Impedance of Testing Transformers.*—For accurate tests, the impedance of the testing transformer should be not greater than 20 per cent based on voltage and current at which the transformer is operated for any test."

Those having Standard No. 4 may obtain an insertion slip covering this change by writing to the standards committee at A.I.E.E. headquarters.

### Proposed Test Code for Synchronous Machines

A proposed "Test Code for Synchronous Machines" was submitted by the Institute's electrical machinery committee to the Institute's standards committee at its meeting of October 11, 1932. Publication of this code, the second in the series originally proposed by the standards committee, was recommended to the board of directors and approved by that body on October 12. The work of publication will get under way at once and a later notice of availability will appear as soon as the date of issue is known. The first code, "Transformer Test Code," has been out for comment since October 1931. There is no charge for copies. Address the standards committee at A.I.E.E. headquarters.

### Lightning Protection Code Is Revised

By the action of the Standards Committee on October 11, 1932, later confirmed by the board of directors, the revision of the "Code for Protection Against Lightning" as submitted by the sectional committee under the chairmanship of Dr. M. G. Lloyd was approved. The original code, developed under the joint sponsorship of the Bureau of Standards and the Institute, was approved by the American Standards Association in April 1929, and was issued as publication No. 92 of the Bureau of Standards. The present revision concerns parts 1 and 2 of the code covering protection of persons and protection of buildings and miscellaneous property. The revised code now will go to the American Standards Association for approval, as recommended by both sponsors, and a new edition eventually will be issued by the Bureau of Standards of the U. S. Department of Commerce.

## Wires and Cables

The 3 standards for wires and cables that were approved by the American Standards Association on May 21, 1931: (1) "American Standard Definitions and General Standards for Wires and Cables" (Revised A.I.E.E. No. 30); (2) "American Tentative Standard Specifications for Weatherproof Wires and Cables" (A.I.E.E. No. 72); and (3) "American Tentative Standard Specifications for Heat Resisting Wires and Cables" (A.I.E.E. No. 73) now are available in pamphlet form. Copies may be obtained through A.I.E.E. headquarters. No. 30 is 30¢ per copy and Nos. 72 and 73, issued as one pamphlet, is 20¢ per copy. A discount of 50 per cent on single copies is allowed to A.I.E.E. members. For a detailed statement relative to these pamphlets, see the August 1932 issue of ELECTRICAL ENGINEERING, p. 599.

# Personal

M. S. SLOAN (A'07, F'30) from 1928 through 1931 president of the New York Edison and affiliated companies, recently was appointed by the United States Chamber of Commerce as chairman of its committee on federal expenditures.

E. W. JUDY (A'26) operating manager of the Duquesne Light Company, Pittsburgh, Pa., recently became a vice-president of the Pennsylvania Electric Association, an organization with headquarters at Harrisburg, Pa.

G. E. LAKIN (A'25, M'30) who has been serving the National Electric Power Company, New York, N. Y., as electrical engineer now has removed to Greenville, Ohio, to become president of the Greenville Electric Light and Power Company.

J. H. SERVICE (A'22, M'30) who has been professor of physics and mathematics at Henderson College, Arkadelphia, Ark., left that position the latter part of September 1932 to become instructor in mathematics and physics at the Michigan College of Mining and Technology, Houghton, Mich.

CALVIN W. RICE (A'97, F'12) national secretary of The American Society of Mechanical Engineers, New York, N. Y., has been appointed a member of the National Research Council on the division of engineering and industrial research for a term of 3 years beginning July 1, 1932.

L. P. MORRIS (A'30) previously special research assistant on the electrical engineering staff of the University of Illinois, (Urbana) recently joined the television engineering department of the U.S. Radio and Television Corporation at Marion, Ind., where he will take up residence.

A. H. MCLEAN (A'21) deputy city electrical inspector of Portland, Ore., will head the Northwest Section of the International Association of Electrical Inspectors as its president for the ensuing year, according to reports from that organization's convention held at Wenatchee, Wash., September 6–8, 1932.

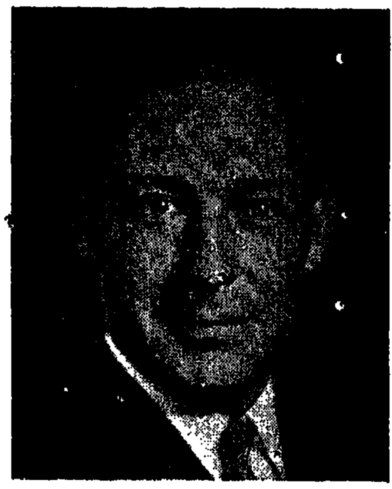
A. S. BROWN (M'30) formerly in responsible charge of all electrical engineering activities for the Federal Telegraph Company, Palo Alto, Calif., recently became associated with the Butte Electric & Manufacturing Company, San Francisco, as its manager. Mr. Brown was born July 1, 1889, in Minneapolis, Minn., received from Montana State College in 1910 the degree of Bachelor of Science in Electrical Engineering, and in 1915 the degree of Electrical Engineer. Before joining the Federal organization November 1928, he had had 7 years of electrical and radio experience with the United States Navy in positions of increasing importance, including service as radio engineer for the U.S. Navy at Mare Island, Calif., Cavite, P. I., Peking, China, and at the Naval Research Laboratory, Washington, D. C.

R. H. MARVIN (A'04, M'29) since June 1926 Engineering Foundation's "Research Fellow in Electrical Engineering" at the Johns Hopkins University, Baltimore, Md., recently became laboratory engineer for the Doble Engineering Company with headquarters at Medford Hillside, Mass. Doctor Marvin was born in Brooklyn, N. Y., October 27, 1879; received his M.E. degree in 1903 from Stevens Institute of Technology, Hoboken, N. J., his M.S. degree in electrical engineering in 1914 from Union College, Schenectady, N. Y., his Doctor of Philosophy from Johns Hopkins University in 1928. Prior to his work at Johns Hopkins he was successively: in the laboratory of the General Electric Lamp Works, Harrison, N. J. (1903–5); test department of the General Electric Company, Schenectady, N. Y. (1905–6); protective apparatus laboratory General Electric Company, Schenectady, N. Y., associated with the development of lightning protective devices and investigation of transmission system disturbances (1906–14); electrical engineer for The R. Thomas & Company, East Liverpool, Ohio, in charge of design and testing of high voltage insulators and line material (1914–18 and 1919–25); and first lieutenant, radio development department, Signal Corps, United States Army (1918–19).

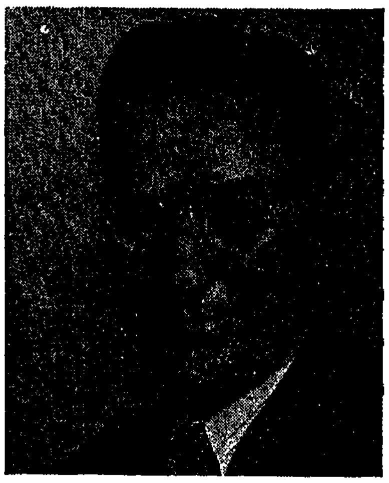
STANLEY STOKES (A'16, M'21, F'29) consulting electrical engineer for the Union Electric Light & Power Company, St. Louis, Mo., was made a vice-president of the Institute representing the South West District (No. 7) by action of the Institute's board of directors, October 12, 1932. Mr. Stokes was appointed to serve until July 31, 1934, filling the unexpired term of G. A. Mills, formerly of Dallas, Texas, but recently removed to Lansing, Mich. Mr. Stokes was born in Columbia, Mo., February 19, 1890; started to school in Cambridge, Mass., while his father was doing graduate work at Harvard University. Continuing through the customary grade schools, he subsequently went to Kirksville (Mo.) State Teachers' College, then attended and subsequently (1912) graduated from the University of Missouri, with the degree of Electrical Engineer representing an additional year's work. In 1910 and 1911 during summer vacations he was with the Telluride Power Company, Utah, on telephone reconstruction work. During this period he received through the Telluride Association a scholarship at Cornell University of which he was unable to take advantage because of financial reasons. During the academic year 1911–12 he was student assistant in physics at the University of Missouri. Since 1912 Mr. Stokes has been associated continuously with his present or affiliated companies: 1912–14 with the Mississippi River Power Distributing Company as material clerk, estimator, and handling sundry other details incident to substation construction in connection with the Keokuk development; 1914–15, with the Electric Company of Missouri on cost analysis, rate schedule, and other such work, acting as assistant to the vice-president; 1915–16, sales engineer for the Electric Company of Missouri; 1916–18, superintendent of the Jefferson (Mo.) division of the Union Electric Light and Power Company in charge of transmission and distribution construction, and the conversion and interconnection of small local plants; 1918–25, manager of the outlying plant division of this company, serving also during this interval as vice-president and

STANLEY STOKES

general manager of the Commercial Telephone Company operating in Franklin County, Mo.; 1925–29, assistant vice-president in charge of electrical engineering and power supervision, in charge of construction of major transmission lines, and responsible to a large degree for important work in connection with the further development of the Keokuk hydroelectric plant and the complete layout of the Cahokia steam-electric generating plant, as well as the interconnection of these plants. Mr. Stokes' activities have included participation in the affairs of the St. Louis Section, for which he has served as secretary and also as chairman of the program committee. His technical writings include "Hinged Wooden Arms Used on Osage-Rivermines Line," published in ELECTRICAL ENGINEERING for February 1932.



J. W. BARKER



R. T. HENRY

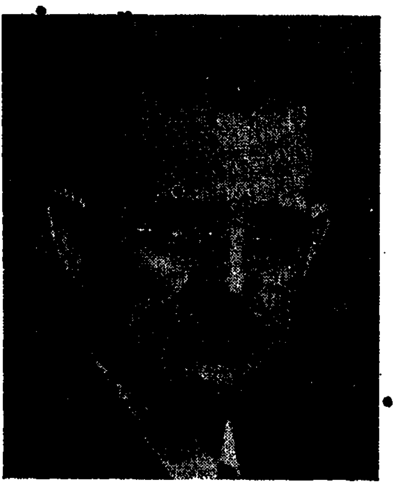
D. W. TAYLOR

**R. T. HENRY** (A'24, M'29) who now is electrical engineer in charge of design for the Buffalo, Niagara & Eastern Power Corporation, Buffalo, N. Y., has been chosen as chairman of the Institute's technical committee on protective devices for the ensuing year. Mr. Henry was born at Stronghurst, Ill., and acquired his preliminary education in the Niagara Falls high school graduating in 1907. He then attended the General Electric engineering school at Lynn, Mass., for one year and subsequently attended a summer session at the University of Michigan. In 1908 he engaged with the General Electric Company, at Lynn, as draftsman, a year later to join the Niagara Falls Hydraulic Power and Manufacturing Company, Niagara Falls, N. Y., in like capacity. In 1912 he became assistant electrical engineer of the Hooker Electrochemical Company, Niagara Falls, N. Y., where he was in charge of electrical construction. The next year he became designing draftsman of the Edison Illuminating Company, of Detroit, Mich., and in 1914 joined the Niagara Electric Service Corporation, Niagara Falls, N. Y., as assistant superintendent. Between 1918 and 1929 he was assistant electrical engineer of the Niagara Falls Power Company, the work involving supervision of the design and construction of additions to the generating stations at Niagara Falls, including 3 32,500-kva units and 3 65,000-kva units, together with the high tension and low tension switching stations, transmission lines, and underground cable systems. Since 1929 Mr. Henry has been electrical engineer in charge of design for the Buffalo, Niagara & Eastern Power Corporation, Buffalo, N. Y., this position really being a continuation of the previous one. Outstanding among the many features which this work has involved is the introduction of the small unit type distribution substation. Mr. Henry is a member of the National Electric Light Association, having been a member of its electrical apparatus committee and chairman of its protective equipment committee. He is a member of the joint committee of the N.E.L.A., A.E.I.C., and N.E.M.A. on oil circuit breakers. He was chairman of the Niagara Frontier Section of the A.I.E.E. for the year following August 1, 1929, and since 1931 has been a member of the Institute's committee on protective devices, of which he is now chairman. Through holding this office he automatically becomes a member of the Institute's technical program committee.

**J. W. BARKER** (M'26, F'30) dean of the engineering faculty at Columbia University, New York, N. Y., since early in 1930, has been elected president of the Illuminating Engineering Society for the year beginning October 1, 1932. Dean Barker was born June 17, 1891, at Lawrence, Mass. He pursued his education to graduation from Massachusetts Institute of Technology, Cambridge, in 1916 with the degree of Bachelor of Science, subsequently taking graduate work (1924–25) that led to his receiving from the same institution in 1925 the degree of Master of Science. After his graduation in 1916 Dean Barker went as a second lieutenant into the coast artillery of the permanent establishment of the United States Army, and was connected with the development of scientific methods in that service. He was a major in heavy artillery in the American Expeditionary Forces and, after the cessation of hostilities in 1918, served various commissions in France, Germany, and the United States. After his return to the United States he continued in the army as a high ranking captain in the Coast Artillery Corps, where he worked on important projects for sound ranging by electric methods. In September 1925, he resigned from the army to accept appointment as an associate professor of electrical engineering at M.I.T., in which capacity he served until 1929. During the academic year 1929–30 Dean Barker was professor of electrical engineering, head of that department, and director of the electrical engineering curriculum at Lehigh University, Bethlehem, Pa. In addition to his activities in the Illuminating Engineering Society he is a member of The American Society of Mechanical Engineers, the American Society of Civil Engineers, and the Society for the Promotion of Engineering Education. In Institute affairs Dean Barker's activities have included membership on the committee on production and application of light (1929–32); committee on education (1930–32); and technical program committee (1932–33).

**D. W. TAYLOR** (A'17, M'23) assistant electrical engineer of United Engineers and Constructors, Inc., Newark, N. J., has been reelected chairman of the Institute's technical committee on automatic stations for the current year. Mr. Taylor's birthplace was Cedar Rapids, Iowa. He attended high school in New York, N. Y., and received his E.E. degree from Columbia University. In 1916 he joined the electrical engineering department of the Public Service Electric Company, Newark, N. J., as cadet engineer. In 1918 he became engineering assistant, working principally on general substation design, system protection, and inductive coordination. As assistant engineer in the electrical engineering department of the Public Service Production Company between 1922 and 1925, he was in charge of relay protection for the system of the Public Service Electric Company. During this same period he also was division engineer in charge of the electrical engineering work for Hudson and Bergen divisions of the Public Service Electric Company. From 1915 to 1927 he was assistant electrical engineer, in charge of electrical design for the central division of the company. In 1927 he became assistant executive head of the electrical engineering department, checking all electrical estimates and supervising all electrical designs. Mr. Taylor was for 2 years a member of the relay subcommittee of the apparatus committee of the N.E.L.A., and was one of the editors of the N.E.L.A. Relay Handbook, writing the section on d-c protection.

**W. C. KALB** (A'12, M'15) since 1928 with the carbon sales division of the National Carbon Company, Inc., Cleveland, Ohio, has been appointed chairman of the Institute's technical committee on electrochemistry and electrophysics for the current year. Mr. Kalb was born at Arcadia, Ohio, and in 1904 was graduated from Ohio State University at Columbus, Ohio, with the degree of M.E. in E.E. After 3 years as mechanical engineer with The Columbus Pneumatic Tool Company, Columbus, Ohio, and a brief period of construction work with the Jeffrey Manufacturing Company, also located at Columbus, he engaged with the National Carbon Company and was placed in charge of its experimental laboratory for brush testing and development. In 1910 he left the National Carbon Company to become superintendent of The Dunlap Engineering Company, at first taking charge of production work and later supervising the sales department. In 1919 he became associated with the Corliss Carbon Company, and as general manager, continued with that company until it was purchased by the National Carbon Company, Inc. Mr. Kalb's present work there is in the advertising and technical publicity activities. His work on the Institute's committees has been continuous since 1929, when he was made a member of the committee on the production and application of light, and since 1931 he has served on the committee on electrochemistry and electrometallurgy, of which he now has become the chairman. He of course serves automatically also upon the technical program committee of the Institute, of which all technical committee chairmen become an integral part.



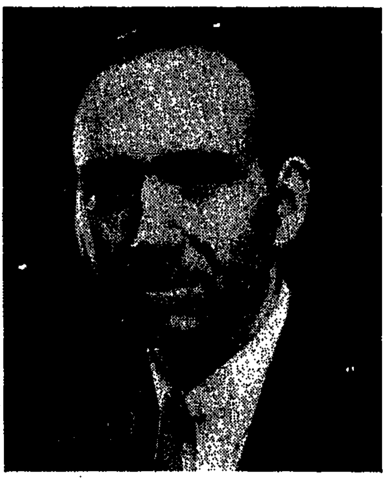
W. C. KALB

W. L. Emmet (A'93, M'94, Member for Life and past-vice-president) consulting engineer for the General Electric Company, Schenectady, N. Y., recently was the recipient of one of the John Scott Medal awards, administered by the Board of City Trusts, Philadelphia, Pa. Doctor Emmet, who already is the holder of over a hundred patents on electrical and kindred apparatus, received this award for his invention of the mercury vapor boiler and its practical application for power purposes. These awards, made annually from a fund established in 1816 by John Scott, a chemist of Edinburgh, Scotland, carry with them besides the medal, a certificate of achievement, and $1,000 in cash. Born at Pelham, N. Y., Doctor Emmet was graduated from the United States Naval Academy at Annapolis in 1881, serving as a cadet midshipman until 1883 aboard the U. S. S. "Essex." In 1887 he joined the Sprague Electric Company, then coping with electric railroad development in various sections throughout the country, and in 1889 was sent to Pittsburgh to superintend one of the largest electric railroad operations of the time. In 1890 he went with the Westinghouse Electric and Manufacturing Company, but only for a short time; he then removed to Buffalo, N. Y., to become electrical engineer for the Buffalo Railroad Company, a position which he again left almost immediately to join the Edison General Electric Company, then just formed, as its district engineer. In 1892 he was transferred to the company's New York office where he started as engineer in charge of the foreign department. In 1898 he re-entered the Navy as junior lieutenant, serving as navigator on the U. S. S. "Justin" during the Spanish War period. In 1900 he started his work of developing the Curtis Steam turbine, the first installation of which at Newport, R. I., proved his great success in this undertaking. Besides the Edison Medal which was awarded him in 1919 for his "invention and development of electrical apparatus and prime-movers," Doctor Emmet has been the recipient of the Franklin Institute's Elliott Cresson Medal "for discovery or original research adding to the sum of human knowledge irrespective of commercial value, of leading and practical utilization," and the Gold Medal of The American Society of Mechanical Engineers, awarded for "distinguished service in engineering and science." He is a member of the American Philosophical Society, the Society of Naval Architects and Marine Engineers, the Naval Consulting Board of the United States, the National Academy of Sciences, and The American Society of Mechanical Engineers.

R. D. Mershon (A'95, F'12, and past-president) recently had conferred upon him, for valuable service rendered the cause of national defense, honorary life membership in the Reserve Officers Association of the United States. The ceremony took place at the annual convention of that association. Mr. Mershon's memberships in technical and scientific organizations include the U.S. national committee of the International Electrotechnical Commission, the Inventors Guild (past-president) the American Society of Civil Engineers, the American Electrochemical Society, the Franklin Institute of the State of Pennsylvania, the Canadian Society of Civil Engineers, The American Society of Mechanical Engineers, the American Association for the Advancement of Science, the British Institution of Electrical Engineers, the Société Internationale des Électriciens, the University Club, Engineers' Club, and Lawyers' Club, of New York, and the St. James Club, of Montreal.

A. H. Babcock (A'04, M'06, F'12) past vice-president of the Institute (1918–19) and for some time consulting electrical engineer of the Southern Pacific (railroad) Company with offices at San Francisco, Calif., retired from office September 1, 1932, after 30 years of continuous service with that company. Mr. Babcock was born at Buffalo, N. Y., August 12, 1865. In the course of his technical training he attended both the University of California, Berkeley, and Lehigh University, Bethlehem, Pa. From November 1891 until July 1898 Mr. Babcock was associated with the San Francisco office of constituent companies of the General Electric group, and from July 1898 until July 1902 was in responsible charge of development work in hydroelectric plants and distribution systems for the Standard Electric Company (Calif.), a pioneer in the California electric utility field. In 1902 he entered the railway field as electrical engineer of the North Shore (Calif.) road, and laid out the first electrification of a steam road to be undertaken on the West Coast. Upon completion of this work he was made electrical engineer of the Southern Pacific system, and later, of all the Harriman lines comprising the rail network from New Orleans and Omaha to the Pacific, and from Spokane, Wash., to Mexico City, and since that time has been responsible for every electrical project of the Southern Pacific. In 1924 he was principal delegate to the Inter-American Commission on Electrical Communication, held in Mexico. As the result of this conference and subsequent discussion with naval officers, he was commissioned for a special service in demonstrating the application of short-wave radio transmission to naval communications. In 1925 he went with the fleet on its Australian cruise, and as the result of his work at that time the navy immediately adapted its communication service to the use of the short waves. Genuinely interested in all new electrical developments, Mr. Babcock also found time for many scientific activities in addition to his regular professional duties. He is a member of the Association for the Advancement of Science and of the Astronomical Society of the Pacific. He is a charter member and past-president of the San Francisco Engineers' Club, and an honorary member of La Sociedad de Geografia Y Estadistica. In addition to serving in other capacities, Mr. Babcock was chairman (1915–16) of the A.I.E.E. San Francisco Section.

F. M. Starr (A'30) of the distribution systems section of the central station engineering department of the General Electric Company, Schenectady, N. Y., has been awarded the 1932 Alfred Noble Prize for his paper "Equivalent Circuits—I," as reported elsewhere in this issue. This paper was presented at the A.I.E.E. winter convention, New York, N. Y., January 25–29, 1932. Mr. Starr was born in Fowler, Colo., in 1905, and was graduated from the university of Colorado in 1928 with the degree of B.S. in E.E. In June 1928 he entered the testing department of the General Electric Company at Schenectady, N. Y., and a year later was transferred to the engineering general department. Two years ago he entered the distribution systems section of the central station engineering department, the position which he now holds. He also has taken the company's 3-year advanced course in engineering.



F. M. STARR

Paul Lebenbaum (A'04, M'13) recently was promoted from assistant electrical engineer for the Southern Pacific (railroad)

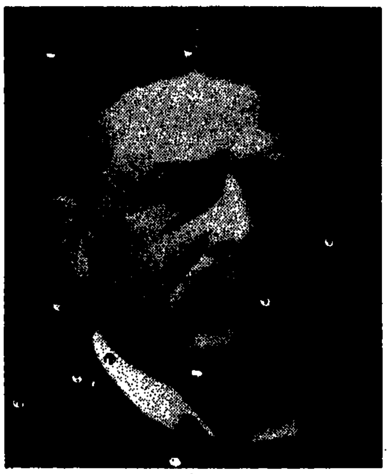
Company, San Francisco, Calif., to the office of electrical engineer for that company to succeed A. H. Babcock who retired as reported elsewhere in this issue. Mr. Lebenbaum was born in San Francisco, Calif., October 20, 1879. After attending the public schools of that city he entered the College of Mechanics at the University of California, Berkeley, whence he graduated in 1902, immediately to join the test department of the General Electric Company. After serving in that department from May 1901 to May 1902, he served in the company's drafting room until October 1902, subsequent to which he spent a year with the North Shore (Calif.) Railroad, during its electrification. Since 1903 he has been with the Southern Pacific Company. Mr. Lebenbaum has been active in Institute circles on the Pacific Coast, and has served the San Francisco Section in various capacities.

S. H. Mortensen (A'09, M'12, F'20) with the Allis-Chalmers Manufacturing Company, Milwaukee, Wis., since 1908 has been appointed by that company as its engineer-in-charge of alternating-current design, succeeding R. B. Williamson who died June 26, 1932, as announced in Electrical Engineering for August. Mr. Mortensen was born in Eskelund, Denmark, November 4, 1878; was naturalized in 1908. After varied and extensive schooling and apprentice experience he graduated in 1902 from Polytechnicum of Mittweida in Germany, with degrees of Electrical and Mechanical Engineer. In the United States he first served with the Westinghouse Electric and Manufacturing Company (1903–5) and next with the Bullock Electric Company of Cincinnati, Ohio (1905–8) before his connection with his present company.

G. A. Mills (M'18) until recently an active leader in Institute affairs in the South West District (No. 7) has moved to Lansing, Mich. Mr. Mills, formerly chief engineer for the Central and South West Utilities Company and vice-president for the Pecos Valley Power and Light Company, Dallas, Texas, now is president of the Michigan Gas and Electric Company and the Michigan Public Service Company. As a result of his removal from the South West District, Mr. Mills resigned his Institute vice-presidency representing that District. Mr. Mills was to have served for the 2-year term, August 1, 1932–July 31, 1934. Stanley Stokes of St. Louis is his successor, as announced elsewhere in these columns. A complete biographical sketch of Mr. Mills is given on p. 54 of Electrical Engineering for January 1932.

L. A. Kelley (A'21) since 1929 a senior engineer on the staff of the International Communications Laboratories, New York, N. Y., now is a partner in the communication engineering firm of Burkholder and Kelley of New York, N. Y., and Toronto, Ontario, Canada. Mr. Kelley's previous experience includes service with the Signal Corps of the United States Army (1918–19); toll systems development department of the Western Electric Company (1920–24); and subsequently the department of development and research of the American Telephone and Telegraph Company. With the I. C. Laboratories Mr. Kelley was engaged in the design and development of new types of communication systems for use by affiliated companies.

H. S. Bennion (M'27) since September 4, 1926, director of engineering for the National Electric Light Association with offices at that organization's headquarters in New York, N. Y., recently was appointed assistant executive director of the N.E.L.A., according to announcement. Major Bennion was born September 7, 1889, at Vernon, Utah. He graduated from the United States Military Academy at Westpoint, N. Y., in 1912, and from the United States Engineers' School, Washington, D. C., in 1915. From graduation his military activities and service on various government commissions, including extensive service in France, continued up to the time of his original appointment to N.E.L.A. in 1926.



G. C. WARD

G. C. Ward (M'24) for 3 years executive vice-president, and since early in 1932 senior vice-president, of the Southern California Edison Company, Ltd., Los Angeles, Calif., has been named its president by action of the company's board of directors, according to press dispatches under date of October 19. As reported in Electrical Engineering (March and April 1932, p. 140 and 213) Doctor Ward has been identified with utility engineering and construction since 1882, and with the Edison Company since 1917 when it absorbed the Pacific Light and Power Corporation of which Doctor Ward was president.

W. A. Danielson (A'09, M'30) major, Quartermaster Corps, United States Army, recently has been assigned to duty as constructing quartermaster with headquarters in Baltimore, Md., from which he will direct construction of hospitals and quarters at Edgewood Arsenal, Camp Holabird and Forts Meade, Howard, and Hoyle. Major Danielson was transferred to Baltimore from Governors Island, New York, where he was on duty as utilities officer for the Second Corps Area. Previously he had been stationed at Washington, D. C.

P. H. Powers (A'21, M'30) vice-president in charge of sales of the West Penn Power Company, Pittsburgh, Pa., recently was elected president of the Pennsylvania Electric Association. Mr. Powers' work with the West Penn interests began in his capacity of division manager of the Keystone Power Corporation at Bellefonte, Pa.; in 1924 he was made general manager of that company and in 1928 he became commercial manager of the West Penn Company at Pittsburgh, Pa. Appointment to the vice-presidency followed in 1930.

H. R. Reed (A'28) has been promoted from assistant to associate professor of electrical engineering in the Michigan College of Mining and Technology, Houghton. Professor Reed went to Michigan Tech. in the autumn of 1929 from South Dakota State College, Brookings, where he had been an instructor since receiving his M.S. degree from the University of Minnesota in 1927. His special field of interest is transient electrical phenomena, in which he conducts senior and graduate courses and carries on research work.

W. P. Schwabe (A'96, M'24) manager and director of the Northern Connecticut Power Company (now affiliated with the Connecticut Light and Power Company) Thompsonville, Conn., and a past-president of the New England Division of the National Electric Light Association, has been appointed a director of the Federal Home Loan Bank for the New England district. His headquarters will be at Cambridge, Mass.

J. C. Burkholder (M'30) formerly chief engineer of telegraphs for the Canadian National Railways, Toronto, Ontario, now is senior partner in the recently formed communication engineering firm of Burkholder and Kelley of New York, N. Y., and Toronto. Mr. Burkholder has been widely known for the successful accomplishment, under his direction, of communication with moving trains, and other related developments.

F. J. Rudd (M'19) who heretofore has been serving the General Electric Company, Schenectady, N. Y., as designing engineer of its motor department, now becomes manager of the stationary motor engineering department upon the transfer of L. E. Underwood (A'03, M'13) to the managership of the Pittsfield (Mass.) works (see Electrical Engineering, October 1932, p. 748).

B. C. J. Wheatlake (A'16) manager of the Salt Lake City, Utah, office of the General Electric Company, has been chosen to care for the arrangements in connection with the Institute's 1933 Pacific Coast Convention, as convention chairman. Mr. Wheatlake already is well known in his local Section activities, in which he has been participating now for some time.

D. W. McLenegan (A'24) who has been serving the General Electric Company at Schenectady, N. Y., as commercial engineer in its industrial engineering department, recently received appointment to the office of assistant engineer of the commercial engineering division of the company's air conditioning department, the formation of which took place only this year.

**E. R. Hedrick** (M'25) professor of mathematics and chairman of the department of mathematics of the University of California at Los Angeles, Calif., has received appointment to the chairmanship of the committee on the teaching of mathematics in colleges and universities of the North Central Association of Colleges and Secondary Schools.

**D. R. Bullen** (A'02) assistant vice-president of the General Electric Company, Schenectady, N. Y., recently was elected second vice-president of the National Electrical Manufacturers Association, New York, N. Y.

**O. A. Demuth** (A'23, M'30) formerly an electrical engineer with the Stone & Webster Engineering Corporation, Seattle, Wash., now is associated with 4 other former Stone & Webster engineers in the Shannon Engineering Company, Seattle, Wash.

**C. W. Mitchell** (M'31) was reelected secretary-treasurer of the southwestern section of the International Association of Electrical Inspectors, at the Santa Barbara, Calif., convention of that organization held September 12–14, 1932.

**R. H. Goodwillie** (A'04) works manager of the Otis Elevator Company, N. Y., recently was elected treasurer of the National Electrical Manufacturers Association, New York, N. Y.

## Obituary

**Charles F. Goob** (M'21) chief engineer for the Baltimore, Md., department of public works, died in Baltimore, September 26, 1932, after a short illness. Mr. Goob was born January 1, 1884, in Baltimore, where he subsequently pursued his education, graduating from the Baltimore Polytechnic Institute in 1901, and completing a postgraduate course there in 1902, in addition to which he pursued a similar course in the mechanical laboratory at Lehigh University, Bethlehem, Pa. From 1902 to 1907 he was successively engaged as a cable tester for the Maryland Telephone Company, draftsman in the chief engineer's office of the Baltimore & Ohio Railroad Company, and draftsman on telephone switchboards for the Western Electric Company at its Hawthorne works, Chicago, Ill. In 1912, acting for the Wilson Maltman Electric Company, he installed all mechanical equipment in the then new Baltimore Polytechnic Institute, where he continued as an instructor of engineering until 1917. From April 6, 1917, until August 31, 1920, Mr. Goob served as an engineer officer in the United States Navy with the rank of lieutenant. Upon his discharge from the navy he became associated with the Electrical Commission of the city of Baltimore as its chief engineer, subsequently heading the bureau of mechanical-electrical service in the Baltimore city government, later becoming the city's chief engineer, a position he filled until his death.

**Cyprien O'Dillon Mailloux** (A'84, M'84, F'12, Life Member, past-president) widely known for his active participation in international engineering and scientific standardization work, and for many years prominent as a consulting engineer in New York, N. Y., died suddenly October 4, 1932, at the age of 71, at his home in that city. Dr. Mailloux was a charter member of the Institute and had served it actively and generously through many years. He served 3 terms as manager (1886–9, 1899–1902, 1905–7) 2 terms as vice-president (1898–9, 1902–4), served as president for the year 1913–14, and devoted many years to the Institute's committees including the standards committee, the Edison Medal committee, and the John Fritz Medal board of award. Dr. Mailloux was born at Lowell, Mass., but at an early age he went to New York City where, in pursuit of professional learning, he was one of the leading pupils of Dr. Pupin who at that time was a lecturer on advanced theory of electrical engineering at Columbia University. In its later application, Dr. Mailloux's professional career touched many and diverse channels. In specifically technical work over a period of 25 years, his activities included "responsible charge" and direction of electrical work on more than 800 jobs ranging from 50 to 25,000 kw; perfection of some 100 inventions of which 30 were patented by him, some of these including patents rated as "basic" in connection with the circuit breaker, the booster for d-c circuits, the non-differential d-c arc lamp, and the iron clad multipolar street-car motor. He spent appreciable amounts of time, in addition to his design and construction work, in the giving of expert advice and counsel, the preparation of statistics and reports, and in arbitration work involving many difficult situations that would have sorely taxed many less capable or less patient and persistent. In this last mentioned capacity his extensive knowledge of languages made it possible for him to be the forceful prominent figure that he became in connection with the first, and many subsequent, meetings of the International Electrotechnical Commission. With his ability as an interpreter and his keen insight he soon found himself in the rather vital rôle of liaison officer. In the I.E.C. Dr. Mailloux has been president (1919–23), director, secretariat on nomenclature, and at the time of his death, honorary president; and on the U.S. national committee of the I.E.C., he has been president (1914–24) chairman, advisor on nomenclature, representative on division of foreign relations. In the International Conference on Large Electric High-Tension Systems in Paris, he was honorary president, acting also as United States delegate at recent biennial meetings. Today the I.E.C. probably is one of the largest cooperative international factors working for the advancement of the electrical profession. Doctor Mailloux was an ardent advocate of a universal language on technical terms—a scientific *esperanto*—which he contended would give the United States, already controlling a heavy percentage of the world's electrical industry, a medium almost invaluable for the promulgation of professional progress. Dr. Mailloux was a liberal contributor to technical literature, and through his effort the electrical engineering nucleus of the present Engineering Societies Library in New York had its origin. In 1902–3 he, himself, donated certain volumes and subscriptions to certain technical periodicals to the library of the electrical engineers, providing maintenance for these sets of books and periodicals by a gift of $1,000 "to be . . . invested . . . the proceeds . . . to be used partly each year for the subscription . . . to the serial publications donated and partly for the binding of said publications." Administration of this fund, still extant and known as the Mailloux Fund, subsequently was modified by the donor to permit the expenditure of moneys accruing from it for "books, periodicals, or other publications in the French language relating to either electrical engineering, mathematical physics and pure mathematics"; its present application represents a still further broadening of these stipulations to include writings other than in French.

**Frederick William Kelley** (A'05) president of the North American Cement Corporation, Albany, N. Y., and former president of the Albany Chamber of Commerce, died September 19, 1932, after a period of continued ill health. Albany was his birthplace (1870) and after attending the Albany Boys Academy for a while, he went to public school in Toledo, Ohio, later also attending the Toledo Manual Training School. In 1893 he was graduated from Cornell University with his degree of M.E.; during this course he took considerable electrical engineering work also but not enough to win him an additional degree. In 1894 he was engaged by the Consolidated Car Heating Company of Albany as draftsman, but so successful a career did he create for himself that he became successively assistant treasurer, treasurer, and general manager of his firm. In 1900 he joined the Helderberg Cement Company of Albany and until 1905 was its vice-president and general manager. In 1925 his company merged with the Security Cement and Lime Company of Maryland and Mr. Kelley who in 1914 had been elected president of his own company now became president of the new organization, the North American Cement Corporation. He later became president of the Portland Cement Association of America. Various other organizations of which he was a member and an officer at the time of his death include: the National Commercial Bank and Trust Company, vice-president; City Savings Bank, trustee; Consolidated Car Heating Company, director (and former president); Albany Hospital, president; Albany Medical College, Albany Academy, Albany Institute of History and Art, and the Dudley

Observatory, trustee; Commercial Safe Deposit Corporation, director; and a member of the board of governors of Union University. Mr. Kelley also held membership in The American Society of Mechanical Engineers, the American Society for Testing Materials, the American Concrete Institute, the Albany Society of Engineers, and the Society of Engineers of Eastern New York, of which he was a past-president.

**Harry Alexander** (A'91, M'17, F'20) long-time electrical contractor with headquarters in New York, died October 18, 1932, at his home in Kings Point, N. Y., as a result of gunshot wounds obviously self-inflicted. It is reported that Mr. Alexander had been suffering for some years from heart trouble. Mr. Alexander was born August 6, 1871, in New York City, according to his A.I.E.E. application made under date of April 21, 1891, although current newspaper reports give Lynn, Mass., as his birthplace. After a common school education he is credited with continuing his education through reading, night study, and practical experience. He was early (1888) connected with the Thomson-Houston Electric Company at Lynn, subsequently becoming a machine shop superintendent for the Thomson Van Depoele Company of Dover, N. H., manufacturers of mining machinery. In the latter part of 1891 he went to New York City as a member of the electrical contracting firm Alexander-Chamberlain Electric Company, which later in the same year became Harry Alexander, Inc. Electrical installations credited to him include the White House in Washington, D. C., and stores and office buildings in various eastern and middlewestern cities including New York, Baltimore, St. Louis, and Boston. He is credited with being the contractor for the original East Side (N. Y.) terminal work of the New York Central Railroad in connection with its Grand Central station (1907); patenting an interior conduit system (1906–7); being a sub-contracting engineer for substation and construction work for the United Railway of Havana (1909); and with patenting the "Alexalite" indirect lighting diffuser (1911). During 1917 and 1918 he was associated with the provision of electric power facilities at the U.S. naval transport terminal in Hoboken, N. J. He was a member of The American Society of Mechanical Engineers.

**Malcolm Percy Ryder** (A'01, M'14) mechanical and electrical engineer at Westfield, Mass., died suddenly May 24, 1932 of heart disease. Mr. Ryder was born in Ossining, N. Y., February 22, 1874, and after high school attendance acquired his early technical education chiefly by home study in conjunction with such practical work as he found. In 1890 he engaged with the Edison Machine Works, predecessors of the General Electric Company, Schenectady, N. Y., taking the student course in shopwork and spending a considerable amount of time in the testing department. In 1892 he went to the Thomas A. Edison iron ore separating works in charge of separators and the electrical plant, a year later joining the General Electric Company's Lynn Works for a special course in arc lighting and a-c work. The year 1893 was spent in Maracaibo, Venezuela, in charge of the central station of the Maracaibo Electric Light Company; then he returned to New York as electrical engineer in charge of the central station of the North River Electric Light and Power Company, later to become its superintendent of central stations for a period of 2 years. The C & C Electric Company of Garwood, N. J., called him as foreman of the winding and testing departments for a year, after which he returned to New York City as wire contractor. In 1899 the New York Edison Company made him superintendent of its Bronx District, a position which he held until 1909, when he removed to Springfield, Mass., to become engineer of the Witherbee Igniter Company, in charge of design and production of ignition apparatus for internal combustion engines. He later invented a novel type of magneto generator which was manufactured by the Witherbee Company. Remaining with this firm until 1919 he then withdrew and took up residence in Westfield, Mass., his home at the time of his death.

**William Lamb Dodge** (M'26) telephone engineer, Bell Telephone Laboratories, Inc., New York, N. Y., died April 7, 1932. Mr. Dodge was born at Clinton, Maine, in 1885, and in 1902 attended Coburn Institute, subsequently winning his degree of A.B. from Colby College, Maine, in 1906. For 2 years thereafter he was engaged in a student course of the Western Electric Company, working also in the installation department of that company. In 1908 he identified himself with the plant department of the New York and New Jersey Telephone Company, a year later joining the plant department of the New England Telephone Company. Here he remained until 1917, when he engaged with the Western Electric Company's engineering department and the Bell Telephone Laboratories, first for the design of manual and machine switching telephone systems, later as engineering department representative in charge of a group of engineers on the first panel machine switching central office placed in service, and still later for $3^1/_2$ years in charge of one or more groups of engineers engaged in the design of machine switching systems of the panel type and the step-by-step type. Mr. Dodge's work has involved the engineering of many important projects and has placed him in charge of highly essential development work.

**J. R. Gilroy** (A'26) injured in an automobile accident May 1, 1932, died September 5 as the result of the accident. Mr. Gilroy was injured at Champaign, Ill., where he had been living while attending the University of Illinois at Urbana. Mr. Gilroy was born in Scotland, June 29, 1903, but pursued his grade and high school education in the United States, after which he graduated from Bliss Electrical School in Washington, D. C., subsequently attending Armour Institute of Technology in Chicago during the period of his employment in the testing laboratory and later in the operating department of the Commonwealth Edison Company of Chicago.

**Neel Bullock** (A'32) who this past summer completed his college course at the University of Alabama, University, Ala., and obtained his degree of B.S. in E.E., was accidentally drowned in St. Andrews Bay, St. Andrews, Fla., August 21, 1932, while out with a boating party. Mr. Bullock was born in St. Andrews, December 20, 1909. He had spent the summer of 1930 in the drafting department of the Southern Kraft Corporation.

# Local Meetings

## Future Section Meetings

**Detroit-Ann Arbor**

November 15, at Jackson, Mich.—SWITCHGEAR. To be discussed by members of the local Section.

December 13, at Detroit, Mich.—ELECTRIC MOTORS AND THEIR APPLICATIONS, by A. M. Dudley, Westinghouse Elec. & Mfg. Co.

**Pittsfield**

November 1—JAPAN, CHINA, AND THE WHITE MAN, by Upton Close.

November 15—AIR CONDITIONING—PERFECT WEATHER IN YOUR HOME 365 DAYS A YEAR.

**Lehigh Valley**

November 18, at Elks Club, Hazleton. THE UNSEEN CONDUCTOR, by Glenn Appleman, Pennsylvania Pwr. & Lt. Co.

**New York**

November 29—Second meeting of the power group: meeting devoted to "Rectifiers and Electronic Devices." C. A. Butcher, Westinghouse Elec. and Mfg. Co., will present "Power Rectifiers" and W. S. Hill, Gen. Elec. Co., will discuss "Power Applications of Electronic Devices." Mercury arc rectifiers, now firmly established in the electric traction field, give promise of becoming practical for low voltage commercial service. Possible application to metropolitan networks will be mentioned. Electronic devices have many present applications and great future possibilities in power and control fields. Distinctions between the various types of tubes together with their applications will be explained. The meeting will convene at 7:30 p.m. and will be adjourned promptly at 9:30 p.m. Non-members are welcome. Discussion is open to all. The location will be Room 1, Fifth Floor, Engineering Societies Building.

## Past Section Meetings

**Birmingham**

Discussion of future plans and reorganization of Section. Election of officers: Howard Duryea, chmn.; H. M. Woodward, secy. Sept. 30. Att. 18.

**Chicago**

Operation of Electrical Machinery in Special Media, by C. J. Fechheimer, consulting engr. Dinner. Sept. 26. Att. 67.

**Cincinnati**

Program Transmission for Broadcasting Stations, by Leo Friedman, American Tel. & Tel. Co. Inspection of the control room in the telephone building. Sept. 22. Att. 112.

**Dallas**

Short talks by B. D. Hull, Southwestern Bell Tel. Co., O. S. Hockaday, Texas Pwr. & Lt. Co., and J. B. Thomas, Texas Elec. Serv. Co. Sept. 19. Att. 50.

**Denver**

Extending Our Frontiers Through Research and Engineering, by H. P. Charlesworth, pres. A.I.E.E., vice-pres. Bell Tel. Labs., Inc. Dinner. Sept. 23. Att. 170.

**Detroit-Ann Arbor**

Hunting Vertebrate Fossils, by Prof. E. C. Case, Univ. of Mich. Dinner. Sept. 20. Att. 68.

**Erie**

Electric Cables, by F. V. Calvert, Gen. Elec. Co. Sept. 20. Att. 25.

**Houston**

The Ultimate Particle, by H. A. Wilson, Rice Institute. Sept. 30. Att. 51.

**Kansas City**

Reports of the summer convention held in Cleveland, Ohio, by A. E. Bettis, Kansas City Pwr. & Lt. Co., R. M. Ryan, Gen. Elec. Co., D. C. Jackson and Robert Warner, both of the University of Kansas. Sept. 26. Att. 65.

**Los Angeles**

Extending Our Frontiers Through Research and Engineering, by H. P. Charlesworth, pres. A.I.E.E., vice-pres. Bell Tel. Labs., Inc. Illustrations. Dinner. Sept. 15. Att. 174.

**Memphis**

Organization and Operation of a Weather Bureau Station, by F. W. Brist, U.S. Weather Bureau Station. Sept. 20. Att. 35.

**Mexico**

Modern Methods of Vertical Transportation, by A. de la Torre, and W. B. Ferguson, Westinghouse Elec. & Mfg. Co. Election of officers: W. A. Schulenburg, chmn.; L. Castro, Jr., secy.; F. Aubert, treas. Sept. 21. Att. 32.

**Montana**

Business meeting. Sept. 16. Att. 12.

**Nebraska**

Prof. M. S. Coover, District Secy., Univ. of Colorado, and Dean O. J. Ferguson, Univ. of Nebraska, spoke on the value of membership in the A.I.E.E. A. L. Turner gave a report of the Summer Convention held in Cleveland, Ohio. Dinner. Sept. 30. Att. 25.

**Niagara Frontier**

Foreign Influences on American Business, by Prof. P. W. Bidwell, Univ. of Buffalo. Dinner. Sept. 16. Att. 55.

**Oklahoma City**

Executive committee meeting. Sept. 2. Att. 11.

Low and Medium Voltage Networks, by Frank Kasper, Byllesby Engg. & Mngt. Corp. Sept. 22. Att. 99.

**Pittsburgh**

The Theory and Operation of the Surge Generator and Cathode Ray Oscillograph, by E. R. Whitehead; Practical Applications and Results Obtained by Use of Surge Generator, by D. B. Perrin. Inspection trip through the laboratories of the Duquesne Light Co. Sept. 20. Att. 220.

**Portland**

Extending Our Frontiers Through Research and Engineering, by H. P. Charlesworth, pres. A.I.E.E., vice-pres. Bell Tel. Labs., Inc. Dinner. Sept. 9. Att. 93.

**Rochester**

Sunlight, by Dr. Brian O'Brien, Univ. of Rochester. Joint meeting with I.R.E. and Rochester Engg. Soc. Oct. 6. Att. 90.

**St. Louis**

Social meeting. Sept. 30. Att. 110.

**San Francisco**

Extending Our Frontiers Through Research and Engineering, by H. P. Charlesworth, pres. A.I.E.E., vice-pres. Bell Tel. Labs., Inc. Sept. 13. Att. 121.

**Saskatchewan**

Recent Developments in Switch Gear, by L. B. Chubbuck, Canadian Westinghouse Co., vice-pres. A.I.E.E. Sept. 7. Att. 27.

Operation of Diesel Engines, by Charles Day, Mirrless Bickerton & Day. Sept. 12. Att. 32.

**Springfield**

Lightning Proof Designs of Transmission Lines, by H. R. Stewart, Westinghouse Elec. & Mfg. Co. Illustrated. Sept. 12. Att. 46.

**Toronto**

The Houses of Life, by Rev. W. J. Johnstone, Eglinton United Church. Sept. 30. Att. 85.

## Past Branch Meetings

**Alabama Polytechnic Institute**

Business meeting. Aug. 29. Att. 20.

The Engineer's Place in the Sun, by Dean W. E. Freeman, Univ. of Kentucky, vice-pres. A.I.E.E. Oct. 6. Att. 31.

**University of Alabama**

Discussion of activities for the coming year. Sept. 26. Att. 20.

**University of Arkansas**

Branch activities were discussed by Prof. W. B. Stelzner, counselor, and L. Wasson, chmn. Sept. 22. Att. 24.

**Bucknell University**

Discussion. Oct. 5. Att. 14.

**University of California**

Power and Economic Basis for Power Transmission, by Prof. W. A. Hillebrand. Film—"A Trip Through the G.E. Plants." Sept. 7. Att. 46.

**Cornell University**

The Organization of the A.I.E.E., by Prof. R. F. Chamberlain; The Early Controversy Between A.C. and D.C. Systems, by Prof. P. M. Lincoln; Photoelectric Cell Applications, by L. F. Moyle, student. Prof. E. M. Strong, counselor, outlined future plans. Oct. 7. Att. 32.

**University of Denver**

Films—"The Electric Ship" and "The Panama Canal." Sept. 27. Att. 20.

**Drexel Institute**

Modern Chain Broadcast Circuits, by J. J. Jaeger, student. Oct. 5. Att. 20.

**University of Florida**

Opportunities in Engineering and How to Prepare for Them, by Prof. Joseph Weil, counselor; Florida as a Come-Back State, by Dean Van Leer. Oct. 3. Att. 90.

**Marquette University**

Board meeting. Sept. 15. Att. 6.

Discussion of proposed constitution. Sept. 22. Att. 13.

Application of Radio to Police Service, by Mr. Wareing, chief engr., Police Radio Broadcasting Dept. Oct. 6. Att. 32.

**Michigan State College**

Business meeting. Oct. 5. Att. 16.

**Mississippi State College**

General discussion. F. G. Marble elected secy. Sept. 22. Att. 27.

**University of Missouri**

Prof. M. P. Weinbach, counselor, outlined the history, purpose, and organization of the A.I.E.E. Raymond L. McGirl elected secy.-treas. Oct. 5. Att. 25.

**Montana State College**

Prof. J. A. Thaler, counselor, outlined the E.E. seminar meetings. R. S. Stokan, chmn., gave a report of the Pacific Coast convention at Vancouver, B.C. R. V. Bauer, student, outlined the purpose and organization of the local Branch. Oct. 6. Att. 101.

**University of Nebraska**

Inspection trip through the power and heating plant of the Lincoln Hotel. Election of officers: John Hutchings, chmn.; Arnold Coffin, vice-chmn.; Charles Devore, secy.-treas. Oct. 5. Att. 22.

**Newark College of Engineering**

Value of Student Societies, by A. R. Cullimore; Branch Activities, by Prof. J. C. Peet, counselor. Sept. 26. Att. 35.

**University of New Mexico**

Election of officers: Stanley O. Fish, chmn., Martin Zirhut, secy.-treas. Oct. 5. Att. 6.

**College of the City of New York**

Business meeting. Sept. 29. Att. 17.

John Ragazzini, chmn., spoke on the advantages of membership in the A.I.E.E. Oct. 6. Att. 34.

**North Carolina State College**

Aims and Purposes of the A.I.E.E., by D. M. House, student; Benefits of the A.I.E.E., by Prof. W. H. Browne, Jr.; Section and District Conventions of A.I.E.E., by Prof. R. S. Fouraker, counselor. Oct. 4. Att. 106.

**University of Notre Dame**

Dr. J. A. Caparo, counselor, outlined the distinction between the local and national benefits of the Institute, and spoke of the advantages afforded by each. Oct. 3. Att. 75.

**Oklahoma A. & M. College**

The Engineering Field in General as Judged From My Experiences, by Prof. J. E. Kirkham. John R. Hollis elected chmn.; Romus Soucek elected vice-chmn. Sept. 19. Att. 26.

**Purdue University**

The Activities and Purpose of the A.I.E.E., by Prof. C. F. Harding; The History of the A.I.E.E. and Its Value to the Student, by Prof. A. N. Topping, counselor; The Indianapolis-Lafayette Section of the A.I.E.E. and the Presenting of Articles to the Branch by Students, by Prof. D. D. Ewing. Sept. 29. Att. 210.

**Rhode Island State College**

Power Distribution in Tall Buildings, by M. Afootian, student. Oct. 5. Att. 20.

**Rose Polytechnic Institute**

Relation of A.I.E.E. to the Student Engineer, by Prof. C. C. Knipmeyer, counselor. Oct. 3. Att. 31.

**Southern Methodist University**

Film—"The Wizardry of Wireless." Oct. 6. Att. 9.

**Virginia Polytechnic Institute**

Flame-Proof Gasoline, by S. L. Butler, student; Electrical Accidents and Their Treatment, by B. G. Belote, student; Niagara-Hudson Power Plant, by H. C. Epperly, student; Electric Machines for Cooling Milk, by B. R. Pogue, student. Oct. 6. Att. 41.

The Great Northern Railway Electrification, by W. P. Swartz, student; Typographs for Bandits, by J. E. Hamm, student; New York City's New Electrical Bank Building, by J. A. M. Maddox, student. Sept. 29. Att. 43.

**State College of Washington**

Dean H. V. Carpenter outlined the proceedings of the annual summer convention held in Cleveland, Ohio. William E. Bratt elected secy. Sept. 30. Att. 15.

**West Virginia University**

Automatic Combustion Control, by C. B. Sims; Direct Reading Ohm-Meter, by G. F. Lefevre; Instrument Transformers, by F. Q. Brown; Use of Electrical Power on Ships, by J. Millard; Air Transportation, by P. M. Vannoy; Electric Service to Morgantown, by L. P. Lovett; History of Michael Faraday, by E. C. McMillan, all students. Sept. 26. Att. 24.

# Employment Notes

## Of the Engineering Societies Employment Service

---

## Men Available

### Combustion

PWR. ENGR., mech. and elec., 43, American, college graduate. Past 3 yr. with prominent engg. organization correlating design engg. work for large central station and industrial pwr. plant projects. Previous 4 yr. rebuilding and operating pwr. plant of large eastern copper refinery. Broad experience. D-986.

### Construction

GRAD. E.E., 29, five yr. supervisory construction, design, estimating and field engg. experience on super-pwr. plants, substations; 4 yr. industrial power plant operation. Elec. construction and maintenance experience; [illegible]y. electrification construction experience. C-4428.

### Design and Development

MECH.-ELEC. ENGR., 32, 4 years' Cornell design instructor; 5 yr. Allis-Chalmers design; liberal shop experience; 5 yr. cooperative apprenticeship. Will consider anything, anywhere. Now available. Salary open. D-122.

JUNIOR ENGR., desires employment where high grade technical knowledge is required. Has had laboratory experience. Familiar with elevator service work and elevator parts design. Go anywhere. C-9963.

ELEC. ENGG. GRAD., 28, married, desires position in design and development or teaching. One year Westinghouse student course; 6 months Westinghouse design school; 1½ yr. design of fractional hp. motors; 2½ yr. design of industrial motors. Available at once. Location, U.S. C-5051.

ELEC. ENGR. and designer, 36, married with 20 yr. experience in pwr. and industrial plant operation, design, estimating and planning. Also experience in traction and mining pwr. supply. Last 7 yr. with leading construction engrs. Good references regarding character, personality, cooperative nature, and ability. Permanent position preferred. Salary reasonable. D-1552.

### Executives

ELEC. ENGR., grad., 42, 5 yr. supervision elec. maintenance r.r. Six yr. head elec. and mech. maintenance group 18 coal mines. Eight yr. assoc. editor coal mining magazine, experienced equipment photography, wide acquaintance, numerous excellent references. B-7563.

ELEC. ENGR., E.E. degree. 14 yr. experience public utilities covering valuation work, rate investigations, engg. pwr. plants, substations, transmission lines, including estimates, specifications, design. Experience covers short circuit studies, stability analysis, investigations of systems for load conditions. Desires position, holding company, operating company, or engg. firm. Available immediately. C-9570.

ELEC. ENGR., married, E.E., M.E. 22 yr. experience, designing, construction pwr. plants substations, transmission, distribution systems, and industrial plants. 3 yr. charge purchasing engineering equipment, foreign interests. 3 yr. exec. experience charge engg. department large utility syndicate. English, German, Russian, Armenian, Turkish languages. Available immediately. D-84.

E.E. DEG., 30. Some training in mech. and civil engg., business administration. Sales experience as district representative handling all local sales activities; special sales representative on sales promotion, and technical sales representative. Elec. testing as asst. elec. engr., Underwriter's Laboratories. Also elec. contracting; building construction and specifications experience. Available immediately. D-1344.

ELEC. GRAD., 38, 17 yr. experience, construction, installation, maintenance, inspection, tests, pwr. plant and substations, distribution (high and low tension), one yr. operating, familiar with South America; speaks several languages. Available at once, home or abroad. Best of references. C-2021.

GRAD. E.E., age 31. Ten yr. experience in public utility and industrial work, covering overhead and underground distribution and transmission installations, electrification of industrial plants, standardization of distribution systems. Headed division for study of industrial plant standardization, also research and analysis pertaining to public utility economics. B-6934.

CANADIAN E.E., 28, single. Would take charge servicing and repair shop, Canada or abroad. 8 yr. practical experience all winding and repair work. 3 yr. supervising, estimates, sales engg. Experience in Westinghouse & G.E. service shops. Can handle men. Licensed as e.e. by professional examination Western Canada. C-8336.

TECH. & BUS. ADMIN. GRAD. Lowell Institute School, auspices M.I.T., elec. and mech. courses; B.B.A. deg. from Boston Univ. also grad. work in management. 14 yr. experience operating, elec. design and engg. Desires position with utility or industrial concern. Location in U.S. immaterial. D-1600.

### Inspection

ELEC. GRAD., 38, single, 6 yr. experience factory testing—W. E. & M. Co., East Pittsburgh, Pa. One yr. steel company installing and testing elec. equipment. 6 months' factory inspection of transformers. 2½ yr. general inspection of elec. equipment with insurance company. Good reference. Available immediately. Any location. D-1461.

### Junior Engineers

1932 GRAD., E.E., B.S., Univ. of Maine. Honor student, Tau Beta Pi, Phi Kappa Phi, 23, single, and excellent physical condition. Best of character. Willing to start at bottom and work up. Wage of secondary importance. Location, Eastern States. Available immediately. D-1509.

B.S., M.S., in E.E., cooperative course, M.I.T., 1932; 22 single. Good scholastic record. Short experience at G.E. machine shop on test and res. lab. Aggressive, willing, capable of assuming responsibility. References available. Location, immaterial. Available immediately. Salary secondary. Interested, any position which requires engg. background and which offers a future. D-1511.

JUNIOR ENGR., grad. Pratt Inst., industrial elec. engg., 24, single, 2 yr. maintenance department N. Y. Tel. Co. 0 months' layout and installation heavy elec. equipment. Available immediately. Location, immaterial. D-1471.

B.E.E., Ohio State Univ., 1932, single, 22. Assoc. member of Sigma Xi. High scholastic record and reading knowledge of German. Specialized in communication work, but will consider any engg. work. Location and salary, immaterial. D-1523.

GRAD. E.E., Columbia Univ., 6 yr. course, 1932; single, 24; desires work with utility, railroad, mfg. concern or construction corp. Would like to teach e.e. subjects. Location and salary, immaterial. D-893.

ELEC. ENGG. GRAD. '31. Desires position on land or water (prefer water) as assistant to pwr. plant operator. Employed at present, mfg., heating and ventilating equipment. Available on short notice. References. Location and salary immaterial providing there is a chance for advancement. D-1535.

1931 GRAD., E.E., B.S., leading western univ., 27, single. Telephone work, machine shop apprenticeship, draftsman and machine designer, familiar with vacuum tubes, good mathematician. Excellent scholastic record. English, German, Swedish, Finnish, and Spanish languages. Desires position with industrial firm. Location, immaterial. U.S. or abroad. Available on short notice. D-923.

ELEC. ENGG. GRAD., M.I.T., S.B., S.M., class of '31, age 23, single. 10 months' test and research experience with G.E. Desirous of a position in e.e. field with chance for advancement. Available at once. Location, immaterial. D-1538.

JUNIOR ELEC. ENGR., B.S., 23, grad. specialized course in a-c and d-c motor and generator engg. and testing, invites correspondence leading to permanent connection with established company desiring to develop production, designing, or equipment engr. Would expect shop experience as training for exec. position later. Location, immaterial. D-1543.

B.S. in E.E. in 1932, age 24, single. Experience in mech. engg., elec. engineering, drafting, and design. Prefer exec. type of work but will consider any position with a future. Location in the East. D-1497.

B.S. in E.E., 1932, 24, single. Desires engg. work of any kind. Salary and location secondary. Available immediately. D-1559.

E.E. GRAD., 1929, 25, single, 2½ yr. experience in design and engg. of high tension outdoor and indoor substations. Desires position connected with hydroelectric development. Location desired, South. C-5967.

E.E. GRAD., M.I.T., B.S. 1931, M.S. 1932, 23, single. 16 months' cooperative training with Edison Elec. Illum. Co. of Boston. Temporarily engaged in retail sales of elec. appliances. Desires connection with utility or mfr. leading to a position in the field of engg. management. Location preferred East or Middlewest. D-1565.

E.E. GRAD., 1932, Rensselaer P.I., 22, single. Desires work in any elec. field. Salary and location, immaterial. Available at once. D-1296.

E.E. GRAD., 1932, Northeastern Univ., 22, single, excellent physical condition. Has had 1½

---

## ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.
San Francisco

205 West Wacker Drive
Chicago

31 West 39th St.
New York

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco. An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

**Men Available.**—Brief announcements will be published without charge, repeated only upon specific request and after one month's interval. Names and records remain on file for three months, renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

**Opportunities.**—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

**Voluntary Contributions.**—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

**Answers to Announcements.**—Address the key number indicated in each case and mail to the New York office, with an extra three-cent stamp enclosed for forwarding.

yr. experience as cooperative student in experimental lab. of radio condenser concern. Desires position in any field of engg. with opportunity for experience. Location and salary, immaterial. Available immediately. D-1571.

UNIV. OF MICH., 1932 grad. B.S. in E.E., 22, single, excellent physical condition. Best of character and hard worker. Two summers with Mich. Bell Tel. Co. Prefers work in elec. field, but interested in management and personnel work. Location, immaterial. Available immediately. Desires position with future. D-1572.

E.E. GRAD., 1932, Miss. State Col., 22, single. Desires engg. work, but will consider anything. Location, immaterial. Available immediately. D-1570.

M.E.; M.S., 26, single. 4 yr. experience in telephone work. Desires teaching or engg. work of any nature except sales. Available immediately. Location, immaterial. D-1225.

1932 CORNELL GRAD., 22, single. Broad education with major in communications. Good scholastic record. Desires work, preferably on telephone, radio or sound equipment. Location desired East. Salary, immaterial. Available immediately. D-1558.

E.E. GRAD., 1932, M.I.T., M.S., 23, single, one yr. G.E. test. Desires work in elec. machine design and development. Available immediately. D-1579.

B.S. in E.E., 1932, 23, single. Desires position with utility or mfg. concern, preferably in field of radio, power transmission, or elec. ry. engg. Will work at anything if only given a chance to enter an engg. house. Available at once, location and salary, immaterial. D-1546.

M.S. in E.E., '32, B.S., '31; Moore School of Elec. Eng., Univ. of Pa. Grad. work in acoustics, electronics and business admin.; teaching experience and experience in the writing of technical papers for publication. Fluent knowledge of German language. Wants responsible work. Location, immaterial; available on one week's notice. D-1585.

GRAD. 1932, B.S. in E.E., Clarkson Col. Grad. 1929 Rochester Atheneum & Mechanic's Inst., diploma in E.E. 2 yr. factory experience in radio and telephone. Desires to work up. Available immediately. Location, immaterial. D-1583.

E.E. GRAD., 1929, Lehigh Univ., married. Post grade work in business finance and sales. Completed 3 yr. cadet engr. training course of Public Service Elec. & Gas Co., involving work in generation, distribution, commercial and sales departments. Excellent references. Desires position with future. Available immediately. D-1566.

B.S. in E.E., 1932, Purdue Univ., single, 21, desires position in any engg. field. Location, immaterial. Available immediately. D-1588.

E.E. GRAD., Univ. of Minn., 1930, 25, single. 2 yr. experience with large midwest pwr. company, including one yr. training course and one yr. distribution and transmission engg. experience. Available immediately. Location and salary, immaterial. D-1590.

E.E. GRAD., Lehigh U., '31, 24, single. 2 yr. experience elec. const., maintenance, repair in utility field. Thorough knowledge a-c network system of distribution. Majored in elec. traction, elec. design. Special training, writing for trade journals, reports. Will accept offer any field. Location, immaterial, foreign service if possible. Available immediately. D-1540.

B.S. and E.E.,'31, Mich. State Col., G.E. test, 4 yr. practical experience with (manual, supervisory controlled, and automatic) pwr. substations, automatic ry. substations (rotary converter and rectifier) and (frame mounted, cell mounted and metal clad) equipment. Willing to do engg., operating, or teaching. D-1597.

B.S. in E.E., 1930, single, 24. Best references following experience: $1\frac{1}{2}$ yr. construction, operation, steam plants, $1\frac{1}{2}$ yr. industrial sales representative N. Y. corporation, 6 months' westinghouse "central station sales" student work. One yr. elec. maintenance work. Recently night engr., refrigeration and ice mfg. plant. Will go anywhere. Suited to utility. Available. D-1599.

**Research**

ENGR., 28, married, B.S., M.I.T. '30 (honor group), Westinghouse engg. school and design school, 2 yr. experience on solution of special problems, stability studies, transmission lines, experienced in use of symmetrical components, Heaviside's theory and general circuit theory. Available immediately. Location, immaterial. D-1530-329-C-1-San Francisco.

E.E. GRAD., Northeastern Univ., cooperative plan, 1931, B.E.E., 24, single, $3\frac{1}{2}$ yr. experience, research and development on syn. elec. clocks for large elec. clock mfr. in East. Has had general engg. experience pertaining to frequency control installation and design. Desires anything in the field. Location and salary secondary. Available immediately. D-1584.

**Sales**

GRAD. E.E. with 12 yr. sales and advertising experience available. Excellent references from leading mfr. and publisher. Middlewest location preferred. Age 34, married. Strong salesman with excellent contacts in Middlewest. B-8614.

DISTRICT SALES MANAGER OR MFR'S AGENT: experienced engg. representative, desires connection with high grade company that has line of industrial or utility equipment. Eastern location preferred. B-4067.

# Membership

## Recommended for Transfer

The Board of Examiners, at its meeting held September 28, 1932, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the acting national secretary.

**To Grade of Fellow**

Caparo, Jose Angel, head, E. E. Dept., Univ. of Notre Dame, Ind.
Hickok, Robert D., pres., Hickok Elec. Instrument Co., Cleveland, Ohio.

**To Grade of Member**

Anton, George F., asst. prof. in E. E. and physics, Univ. of Porto Rico, Mayaguez, P. R.
Dible, Harvey J., transmission and protection engr., Ohio Bell Tel. Co., Cleveland.
Dow, William G., asst. prof. of E. E., Univ. of Michigan, Ann Arbor.
Edgerton, Harold E., asst. prof. of E. E., Mass. Inst. of Tech., Cambridge.
Lockwood, Earle L., distribution engr., Pub. Serv. Co., Newport News.
MacGregor, Willard H., 217–22 Bayside Blvd., Bayside, L. I.
Milton, Robert M., asst. E. E., U.S. Engr. Office, New Orleans, La.
Noertker, Joseph A., E. E., Cincinnati St. Ry. Co., Ohio.
Pike, Noel, dist. pwr. supt., Guanajuato Pwr. & Elec. Co., Guanajuato, Gto., Mexico.
Reukema, Lester E., assoc. prof. of E. E., Univ. of California, Berkeley.
Schregardus, Dirk, transmission engr., Ohio Bell Tel. Co., Cleveland.
Thomas, Richard N., Borough E. E., Lyttelton, N. Z.
Watson, Malcolm Vau, vice-pres. and genl. mgr., West Coast Pwr. Co.; Calif. Pub. Serv. Co.; Western States Utilities Co., Portland, Ore.

## Applications for Election

Applications have been received at headquarters from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the acting national secretary before Nov. 30, 1932.

Anderson, L. F., Hotel Riviera, 169 Clinton Ave., Newark, N. J.
Benson, I., 57 Ashland Ave., East Orange, N. J.
Bozenschultz, E. J., The Home Tel. & Tel. Co., Ft. Wayne, Ind.
Brandler, A. B., Royal Switchboard Co., N. Y. City.
Cooper, R. E., Jr., Air Corps, U. S. A., March Field, Calif.
Donovan, A. C., Jr., 34 Manchester Rd., Brookline, Mass.
Eash, C. D., (Member), Consumers Pwr. Co., Jackson, Mich.
Erskine, G., Erskine Elec. Wk., Redwood City, Calif.
Foerner, G., 11 a, West End Ave., Bklyn., N. Y.
Forbes, A. F., Newport News Shipbuilding & Dry Dock Co., Va.
Hield, R. F. (Member), Crompton Parkinson, (Canada), Ltd., Montreal.
Kramer, J. E., Kramer Bros., San Francisco, Calif.
Laverty, C. A., Boiler Inspection & Ins. Co., Montreal, P. Q., Canada.
Lee, J. D., Jr., 19 Marine Ave., Bklyn., N. Y.
Martin, H. E. Waterbury Cable Serv., Inc., N. Y. City.
McRae, D. M., Grain Ins. & Guarantee Co., Winnipeg, Manitoba, Can.
Meltvedt, H., (Member), 421 Franklin St., Downers Grove, Ill.
Miller, A. P., 111 Fulton St., Bloomfield, N. J.
Murray, T. E., Jr., (Fellow), Metropolitan Eng. Co. & Metropolitan Device Corp., Brooklyn, N. Y.
Peterson, G. C., 15 Douglas Place, Verona, N. J.
Rosin, A., (Member) Boro. of Richmond, Clove Pumping Sta., Ontario St., Staten Island, N. Y.
Stanley, C. M., Young & Stanley, Inc., Muscatine, Iowa.
St. Laurent, H., Radio Research Lab., Inc., Yonkers, N. Y.
Travis, I., Univ. of Pa., Philadelphia.
Van Sickle, L. R., 416 E. 17th Ave., Denver, Colo.
25 Domestic

### Foreign

Alizo, C., Antonio Cia., Annma., Planta Elec. de Valera, Est. Trujillo, Venezuela, S. A.
Foulsum, W. C., 16 Bondoran Parade, Mont Albert, Melbourne, Australia.
Kesavan, K. V., Pwr. Station, Kottayam Travancore, So. India.
Lautier, V., 37 Sda. San Paolo, Cospicua, Malta.
Rozario, J. F. T., Pub. Wks. Dept., Madras Govt., Madras, India.
Sarda, P. M., Ratan Pole, Nagori Pole, Ahmedabad, India.
Singh, H., Simla Municipal Committee Idgah, Simla, India.
Swami, T. V., Elec. Dept., Cocanada, India.
Tharani, J. J., Elec. Pwr. House Veraval, Kathiawar, Manavadar, India.
9 Foreign

# Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the address as it now appears on the Institute records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Bohner, C. W., 620—22nd Terrace, Miami, Fla.
Brock, Geo., 1117 N. 15th St., Milwaukee, Wis.
Dalas, F. L., Boulder City, Nev.
Deney, Roger W., 685 Sumner-Atlantic Ave., Forest Hills Boro, Pittsburgh, Pa.
Florez-Estrada, Jose, Avenida De La Paz 60, Reparto Alture-Rio Almendares, Marianao, Havana, Cuba.
Gooding, Chas. C., 1414 K St., Sacramento, Calif.
Jefferson, H. F., 633 Portola Ave., Glendale, Calif.
Keiser, Morris, 1025 King St., Alexandria, Va.
Keller, Dr. Max Leo, Kornweg 8, Aarau, Switzerland.
McShane, Joe B., 810 Western Natl. Bldg., San Antonio, Texas.
Newman, Rexford C., 100 High St., St. Clairaville, Ohio.
Nimetz, John B., 3442 Sacramento St., San Francisco, Calif.
Olsen, V., P. O. Box 404, Shanghai, China.
Peterson, Alex., Central West Pub. Serv. Co., Omaha, Nebr.
Richardson, Jas. Ray, 223 Sheldon Ave., S.E., Grand Rapids, Mich.
Schatz, Nathan, 1845—52nd St., Brooklyn, N.Y.
Shen, C. Mayo, 18 an Check L8, Scott Rd., Shanghai, China.
Thomas, Alfred J., c/o L. J. Healing & Co., Ltd., Yusen Bldg., Tokyo, Japan.
Uline, Wm. A., Northern Elec. Co., Guy & Notre Dame Sts., Montreal, Que., Can.

# Engineering Literature

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statement made; these are taken from the preface or the text of the book.

All books listed may be consulted in the Engineering Societies Library.

ARCHIV FÜR TECHNISCHES MESSEN. Lieferungen 13–14, July-Aug., 1932. Munich and Berlin, R. Oldenbourg. Illus., 12x9 in., paper, 1.50 rm. each. Section of a comprehensive work which is being published serially on methods of technical measurement and measuring instruments. Each number contains brief articles by specialists; also usually bibliographies. Punched for loose-leaf binder and classified for convenient reference.

CHEMICAL ENCYCLOPAEDIA. By C. T. Kingzett. 5 ed. New York, D. Van Nostrand, 1932. 1014 p., 9x6 in., cloth, $10.00. A convenient one-volume reference work in nontechnical language intended primarily for merchants, manufacturers, and all interested in chemical processes; also useful to professional chemists for rapid reference. A brief, clear account of almost every chemical substance of practical importance.

CHROMIUM PLATING. By E. S. Richards. Phila., J. B. Lippincott, 1932. 131 p., illus., 8x5 in., cloth, $3.50. Intended for those responsible for plating plants and devoted to the practical production of the plate and methods for ensuring regular outputs of good work. Shop equipment and methods of preparing, plating, and finishing work described in detail.

DIESELMOTOREN IN DER ELEKTRIZITÄTSWIRTSCHAFT INSBESONDERE FÜR SPITZENDECKUNG. By M. Gercke. Berlin, Julius Springer, 1932. 92 p., illus., 10x6 in., paper, 6 rm. A study of the suitability of Diesel engines for electric power plants and of the extent to which they have been used. The author gives data upon plants throughout the world, discusses advantages of the Diesel as standby and peak load equipment, and compares its economy with that of steam equipment.

EINFÜHRUNG IN DIE METALLOGRAPHIE. By P. Goerens. 6 ed. Halle (Saale), Wilhelm Knapp, 1932. 392 p., illus., 10x7 in., paper, 15.50 rm.; bound, 17 rm. Since the fifth edition of this book much has been done to clarify the theory of metallography and to extend its practical use. These advances have been used in the revision. A new chapter on the X-ray examination of metals is incorporated. Practical application of metallography in iron testing has been enlarged upon and the advantages of metallographic investigation in studying flaws emphasized.

EINFÜHRUNG IN DIE THEORETISCHE KINEMATIK. By R. Müller. Berlin, J. Springer, 1932. 124 p., 9x6 in., paper, 6.80 rm. This textbook presents the course given by the author at the Darmstadt Tech. Col. It is intended primarily for students of mechanical and electrical engineering, but is adapted also to students of mathematics. Presents theoretical principles underlying machine design, in general purely geometrical.

ELEKTROTECHNICKÁ ROČENKA ESČ 1932. By B. Pařez. Prague, Elektrotechnický Svaz Československý, 1932. 320 p., illus., 12x9 in., cloth, Kc 200. The yearbook of the Czeschoslovak Electrical Society giving a complete description of the condition of the electrical industry in the country, and containing regulations governing electric utilities; very complete statistics upon light and power, radio, telephones, etc.; lists of manufacturers and other data of value to engineers.

ELEMENTS OF PHYSICS. By A. W. Smith. 3 ed. New York & London, McGraw-Hill, 1932. 778 p., illus., 9x6 in., cloth, $3.50. A college textbook giving a survey of the field of physics with considerable emphasis upon modern physics. An endeavor to encourage the student to form physical images of the principles presented and to apply them to the explanation of every-day experiences. Applications of physics to agriculture, engineering, and every-day life are used largely to illustrate the principles.

ENCYCLOPAEDIA OF OXYACETYLENE WELDING. 2 v.; V. 1. Pipe Construction. 83 p. V. 2. Construction of Apparatus and Containers. 80 p. Geneva, Switzerland, International Advisory Committee for Carbide and Welding Technique. (Gift of Acetylene and Welding Consulting Bureau, Ltd., London). 1932. Illus., 12x9 in., cloth, 10s.6d. The first 2 vol. of a series of 6 forming an album on the applications of oxyacetylene welding. Each volume contains about 80 plates of welded structures, and brief explanations in 5 languages. The engineer or manufacturer will find the work interesting and suggestive of many uses for the process.

FEDERAL RADIO COMMISSION, Its History, Activities, and Organization. (Inst. for Government Research, Service Monographs of the U.S. Govt. No. 65.) By L. F. Schmeckebier. Washington, Brookings Institution, 1932. 162 p., 9x6 in., cloth, $1.50. A monograph giving an accurate account of the history and development of the Commission, describing its specific activities in detail and explaining its organization. The regulations governing its work, its appropriations, and expenditures, are presented; with a full bibliography.

HEAT-TREATMENT AND ANNEALING OF ALUMINIUM AND ITS ALLOYS. By N. F. Budgen and D. Hanson. London, Chapman & Hall, Ltd., 1932. 341 p., illus., 10x6 in., cloth, 25s. The theories of hardening and strengthening aluminum alloys, practical methods, and equipment for thermal treatment, its effects upon the physical properties of wrought and cast material, and the annealing of wrought and cast aluminum and its alloys, are discussed comprehensively for the first time. Scattered information is collected and presented for practical use. Dr. Budgen is superintendent of a large English aluminum foundry.

INDEX TO THE LITERATURE OF FOOD INVESTIGATION. V. 4, No. 1, March 1932. London, Gt. Britain, Dept. of Scientific and Industrial Research. 135 p., 10x6 in., paper, 2s. 6d. (Obtainable from the British Library of Information, 270 Madison Ave., New York, $.70.) This index, printed every 6 months, is useful to all those concerned with food production and preservation. Nearly 100 periodicals are covered, entries are classified conveniently, and annotations provided. The engineering section will be found useful as a bibliography of investigations of refrigeration and air conditioning.

INTERIOR AND EXTERIOR LIGHTING. By C. E. Weitz. Scranton, Pa., International Textbook Co., 1931. Pt. 1, Interior Lighting, 41 p.; Pt. 2, Exterior Lighting, 77 p., illus., 8x5 in., cloth, $1.75. A description of modern lighting practise, advising choice of methods and fixtures, standards of illumination for various purposes, and similar matters. A help to those wishing elementary advice in concise form.

INTRODUCTION TO PHYSICAL SCIENCE. By C. W. Miller. New York, John Wiley & Sons, 1932. 403 p., illus., 9x6 in., cloth, $3.00. To provide an elementary text that will offer the necessary fundamental training and at the same time give a broader outlook on modern physics. An effort to lead the student by natural steps from the beginnings of scientific thought to the results of modern research. The text is clear and definite. Mathematics beyond the high school stage are omitted.

LICHTBOGEN - STROMRICHTER FÜR SEHR HOHE SPANNUNGEN UND LEISTUNGEN. By E. Marx. Berlin, J. Springer, 1932. 167 p., illus., 9x6 in., cloth, 18.50 rm. A book to show that it is possible to transform and rectify high voltage currents by means of arcs burning in currents of compressed air. The principles underlying this rectifier and practical methods for constructing arc rectifiers are presented, based largely upon the investigations of Prof. Marx and his colleagues at the Braunschweig Technical High School.

MACRAE'S BLUE BOOK, consolidated with Hendricks' Commercial Register. 40th Annual Edition. Chicago and New York, MacRae's Blue Book Co., 1932–1933. 3333 p., illus., 11x9 in., cloth, $15.00. A buying guide for manufacturers, railroads, mines, municipalities, public utilities, contractors, engineers, and mills. Materials are fully classified and well indexed, with a directory of manufacturers and local distributors, a section describing the trade facilities in towns of more than 1,000 inhabitants, and a directory of trade names. A section is devoted to Canada.

MITTEILUNGEN AUS DEN FORSCHUNGSANSTALTEN DES GHH-KONZERNS, Band 2, Heft 2, July 1932. Berlin, VDI-Verlag. 35–56 p., illus., 12x9 in., paper, 2.50 rm. This number gives a description of a new spectrum photometer and its use for the rapid analysis of alloys, especially iron; an article on the resistance of welded bars, a comparison of the calculated resistance of ships with the results of tests on models, and an essay on entropy and probability.

MODERN MATERIALS HANDLING. By S. J. Koshkin. New York, John Wiley & Sons, 1932. 488 p., illus., 9x6 in., cloth, $6.00. A large amount of condensed information in convenient form upon modern methods and equipment for handling materials in factories. Cranes, overhead transporters, trucks, conveyors, hoists, coal, and ash handlers, etc., are considered. Methods of handling different materials and the choice of equipment for any given purpose are discussed.

MODERN PHYSICS. By G. E. M. Jauncey. New York, D. Van Nostrand, 1932. 568 p., illus., 9x6 in., cloth, $4.00. Intended for the student with one year of college physics and mathematics, and directing attention to X-rays, the quantum theory, cosmic rays, relativity, radioactivity, astrophysics, and similar topics. The book is designed to give the student some knowledge of the parts of physics which are now in process of active formation or only recently developed.

NOMOGRAM, the Theory and Practical Construction of Computation Charts. By H. J. Allcock and J. R. Jones. London & New York, Isaac Pitman & Sons, 1932. 209 p., 9x6 in., cloth, $3.00. The authors discuss the general theory of nomograms and give practical directions for making and using all classes of computation charts of scientific or industrial usefulness. The book covers the field satisfactorily and will be welcomed by calculators.

PHOTOCELLS AND THEIR APPLICATION. By V. K. Zworykin and E. D. Wilson. 2 ed. New York, John Wiley & Sons, 1932. 331 p., illus., 8x5 in., cloth, $3. The theory of the photoelectric cell, its manufacture, and its use in picture transmission, television, sound production, and for other industrial purposes, are set forth concisely, yet comprehensively. A book useful to the untrained reader as well as to the specialist. The new edition has been revised thoroughly and 5 new chapters added.

RADIO ENGINEERING. By F. E. Terman. New York & London, McGraw-Hill, 1932. 688 p., illus., 9x6 in., cloth, $5. This textbook aims to present a comprehensive engineering treatment of the more important vacuum tube and radio phenomena for the senior year of an electrical engineering curriculum. The first part of the book is devoted to the theory of tuned circuits, the fundamental properties and the applications of vacuum tubes of importance to all electrical engineers. The second part discusses more specialized radio topics, such as radio receivers and transmitters, wave propagation, antennas and direction finding.

SYMPOSIUM on RUBBER: Cleveland, Ohio, March 9, 1932. Philadelphia, Am. Soc. for Test. Mats., 1932. 160 p., illus., 9x6 in., paper, $1.75.—The papers deal with the manufacture of rubber products and the properties of rubber as an engineering material. Topics discussed include properties of crude and reclaimed rubber, vulcanization, compounding, reinforcing, flexing of rubber products, shock and vibration properties of rubber, deterioration under friction, resistance to water, chemicals and electrical characteristics, and uses as an adhesive.

Die TECHNISCHE ELEKTROLYSE WÄSSERIGER LÖSUNGEN. (Handbuch der technischen Elektrochemie v. 1, 2 pts.) By V. Engelhardt. Leipzig, Akademische Verlagsgesellschaft 1931–32. Pt. 1, 613 p., 52 rm., cloth; Pt. 2, 331 p., 32 rm., cloth, 10x7 in.—With the assistance of German and American specialists, Dr. Engelhardt has undertaken the preparation of a comprehensive, systematic treatise upon the technical uses of electrochemistry and electrometallurgy. This, the first of 5 vols., is devoted to the electrolysis of aqueous solutions. General discussion of theoretical principles and a general review of apparatus (baths, electrodes, diaphragms, etc.) open the volume; then attention is turned to the electrometallurgy of aqueous solutions. The electrolysis of industrial metals is then discussed by various experts. Throughout, attention is concentrated upon present practise, and much note given to descriptions of modern plants, plant and operating costs, and statistics of production and prices. Bibliographies included. Useful to all in search of practical information.

**Engineering Societies Library**

29 West 39th Street, New York, N. Y.

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable and an inquiry to the director of the library will bring information concerning them.

# Industrial Notes

**M. P. Ellis Resigns From Steel & Tubes, Inc.**—Announcement has been made by Morgan P. Ellis, of his resignation as general sales manager of Steel & Tubes, Inc., Cleveland, O. Mr. Ellis has not revealed his plans for the future.

**Engineering Firm Opens Cincinnati Office.**—The Burns & McDonnell Engineering Co., consulting engineers, has opened an office at 612 Dixie Terminal Bldg., Cincinnati, in charge of C. F. Lambert, a member of the firm. This company has been established at Kansas City for thirty-five years, and has had an office in Los Angeles for the past ten years. The firm specializes in municipal engineering, including electric light plants, water works, sewer systems, investigations, appraisals, and reports.

**Ball Bearing Sales Consolidation.**—The Marlin-Rockwell Corporation has consolidated the sales activities formerly carried on independently by its subsidiary companies—Gurney Ball Bearing Division, Standard Steel & Bearings, Inc., and Strom Bearings Co. The bearings manufactured by these companies will hereafter be marketed through the corporation's sales organizations, with offices at Jamestown, N. Y., Plainville, Conn., and Chicago. Branch sales offices will be maintained at the former addresses in Detroit, Cincinnati, Cleveland, Los Angeles, and San Francisco. A new branch sales office has been opened at 40 W. 63rd St., New York.

**New York Offices for Amerika-Interessen, Inc.**—Offices have been opened in the Chrysler Building, New York, by Amerika-Interessen, Inc., organized as the American unit of A. G. Fuer Amerika-Interessen, operating also in Berlin, Paris, and London. According to Botho Bilienthal, president, in order to surmount tariff barriers, the corporation plans to make available to the manufacturers of one country such devices, processes and patents that have been proved successful in other countries. For manufacturers who wish to augment their incomes by obtaining business abroad, but cannot do so by exports, agreements are negotiated covering production and marketing rights. This is done by issuing licenses on a royalty basis or by the outright sale of the manufacturing and marketing rights for the country involved. The American company's engineers have selected from over 1,000 offerings, about 100 devices that seem suitable for immediate exploitation in this country. These are in many fields and include such widely different lines as machine tools and appliances, electrical devices, temperature indicators and recorders, optical instruments, advertising displays, air conditioning equipment, welding processes, steel house construction, etc.

**Splash-Proof Motor.**—The Louis Allis Co., Milwaukee, has introduced a splash-proof motor safeguarded to prevent entrance of water splashed with terrific pressure from any angle, yet adequately ventilated and built in the same dimensions as a standard open motor. A double baffle in an elliptical-shaped air passage in each end-bell provides the unusual protection offered by this new motor. The unique construction permits free passage of ventilating air yet traps and drains water splashed into the air openings at the bottom of the elliptical-shaped chambers. Another original feature is a shaft guard which breaks the force of a stream directed along the shaft extension and prevents water from entering the bearing chamber.

**New Circuit Breaker.**—The Delta-Star Electric Co., Chicago, announces a new 5 kv, 3,000 amp, 50,000 kva three-pole, non-oil throwing type, indoor oil circuit breaker. The welded square tank with full rounded corners, is fabricated of heavy steel plate, thoroughly reinforced and banded. The interior is completely lined with arc-resisting material. The straight line motion mechanism, composed of non-magnetic steel parts, operates under a heavy, Everdur domed tank head, eliminating magnetic heating. The terminals and bushings are made of copper bars with wrapped, impregnated, bakelized paper. These terminals are held to the domed head by means of non-ferrous clamps. The breaker lift rods travel through roller guides, insuring positive alignment with low friction losses, and high speed of contact operation.

**Another Burndy Lug.**—Continuing on a program of developing connectors for wires and cables based on the clamp type principle, the Burndy Engineering Co., Inc., New York, has developed a clamp type lug that possesses new features which minimize installation costs. To install the new type of Burndy lug requires only a wrench and a minute or two of time. The compression principle used provides contact over a large cable area in close intimacy with the contact tongue of the lug. Designs of the new device for all standard wire and cable sizes, as well as odd combinations of angle connections for single and multiple conductors have been prepared. Since its introduction there have been a number of notable installations, including the use of thousands of the lugs in the Rockefeller Center group of buildings in New York.

**New Electrostatic Voltmeters.**—A complete line of electrostatic voltmeters, designed to provide a ready means for measurement of high d-c and a-c voltages, particularly in circuits of high resistance where any appreciable current taken by a voltmeter introduces considerable error, has been developed by Ferranti, Inc. The instrument is entirely free from wave form, frequency and temperature errors, and is available in the single range projecting, flush or portable types, fitted in $2^1/_2''$ moulded bakelite cases. The meter can be supplied in nine different ranges having full scales from 450 volts to 3,500 volts, the capacity ranging from 30 micro-microfarads with full scale deflection for the 450-volt meter, to 5 micro-microfarads for the 3,500-volt instrument. The meter is designed with an 80° scale readable to the unusually low figure of 20% of the full scale value.

A safety resistance of high value is fitted inside the case of each instrument to limit the current in the event of a flash-over due to over-voltage. This resistance renders the meter free from damage to over-load provided that the over-load is maintained for only a short time. The Ferranti electrostatic voltmeter is essentially a variable condenser, and although there is a minute current passed by the instrument on alternating current circuits, there is no power loss as the current is 90° leading with respect to the voltage and has no "in-phase" component. The instruments are magnetically damped, and have reasonably high torque for this class of meter.

# Trade Literature

**Uses of Hard Rubber in Industry.**—Catalog 1, 18 pp. Describes hard rubber products for industrial purposes. Illustrations include applications in electrical manufacturing. American Hard Rubber Co., 11 Mercer St., New York.

**Midget Motors.**—Bulletin, 4 pp. Describes "Barcol Midget" shaded pole induction motors. Other bulletins on two-pole and four-pole undirectional motors and two-pole geared-head, and reversing motors, 1–100 hp and less, are also available. Barber-Colman Co., Rockford, Ill.

**Constant-Tension Drive.**—Bulletin 602, 4 pp. Describes the Reliance automatic tension regulator for application to any process requiring a constant tension in material being wound or unwound from a reel. Reliance Electric & Engg. Co., 1088 Ivanhoe Rd., Cleveland, O.

**New Metering System.**—Bulletin 1960, 8 pp. Describes a new metering system combining the advantages of the new OC detachable watthour meter, the new portable stroboscopic standard, and the nofuse load center. Each of these pieces of equipment is illustrated and its use in the system explained. The field testing method provided by the stroboscopic standard constitutes a new element in metering. Westinghouse Elec. & Mfg. Co., Newark, N. J.

**Ratchet Type Relay.**—Bulletin CX 464. Describes the "Dunco" ratchet type, or sequence relay. The energizing of the coil moves the pawl, engaging a ratchet which actuates a cam or cams to open or close the contacts. By a minor adjustment of the cams moving the contacts together, these relays can be made single pole, double break; double pole, single break; or single pole, single break, double throw. Relays can be furnished for various voltages, alternating or direct current. Struthers Dunn, Inc., 139 No. Juniper St., Philadelphia, Pa.

### Front Cover

An electric passenger train leaving the west end of the famous Cascade tunnel on the Great Northern Railway in Washington. The tunnel is 7.79 miles long and cost $14,000,000 to build; it was completed early in 1929. The locomotive is of the single-phase motor-generator type operating on 11,000 volts, and weighs 260 tons.

PULP insulation may now be applied directly to the conductor of a telephone cable, the paper making and insulating operations being combined into one process. A considerable saving over spirally wrapped paper insulation is made possible by the use of a low cost Kraft pulp and the elimination of the paper making, paper splitting, and handling operations. *p. 838–43*

DISCUSSIONS of the technical papers presented at the Institute's Middle Eastern District meeting, Baltimore, Md., October 10–13, 1932, have been reviewed and summarized. *p. 877–9*

UNLIMITED range is available in a new electrostatic voltmeter for measuring either a-c or d-c potentials. It is a rugged and portable instrument, has high accuracy, short period, linear scale characteristics, and draws no current. *p. 863–5*

LIGHTNING protection has been carefully considered in the design of the Safe Harbor-Westport 230-kv transmission line. Insulation is particularly heavy, ground wire protection has been applied according to the latest theory, and special effort has been made to reduce tower to ground resistances. *p. 834–8*

SYNCHRONOUS motors applied to constant speed main-rolls in metal rolling mills, both steel and non-ferrous, are rapidly increasing in favor, due to improvements in the synchronous motor and its control, and the favorable first cost. *p. 855–8*

FAULT location on power cables has been facilitated by one company through the use of constant current transformer for reducing high initial fault resistance, and a short circuiting switch for generating signals which locate the fault. *p. 870–2*

QUICK stopping of synchronous machines usually can be accomplished most satisfactorily by dynamic braking. Accurate prediction of the number of revolutions and time required to stop now can be made by means of simple formulas. Changes in excitation during the stopping period are taken into account. *p. 843–5*

ECONOMIC aspects of water power have been analyzed to facilitate comparison between hydroelectric and steam plants. The capacity and energy costs of hydroelectric power are expressed in terms of the cost of steam power, and various factors affecting any decision as to whether a hydroelectric or steam power plant is to be built are discussed. *p. 849–52*

METAL transfer during electric arc welding, although subjected to much discussion, is not fully understood. The mechanism of this transfer has been studied by a new method which it is stated records all of the possible forms of metal transfer, by means of a metallic strip moving at high speed through the arc. This method indicates that liquid globules are the chief form of metal transfer. *p. 852–4*

CHANGES have been made in the prizes which the Institute presents for technical papers. These changes concern the prizes for national, Section, and Branch papers. Although the cash awards have in some cases been eliminated, ample incentive for the preparation of well written papers should remain. *p. 875*

TECHNICAL papers to be presented at the 13 sessions of the Institute's coming winter convention to be held in New York, N. Y., January 23–27, 1933, have been tentatively arranged. The subject balance of these papers is particularly good, and should draw many to attend the convention. *p. 873–4*

ACTIVITIES in unemployment relief during the winter 1931–32 were summarized in ELECTRICAL ENGINEERING for November 1932, p. 809–13. Supplementing this article, suggestions which have been received from many Sections of the Institute, giving methods which may be followed during the coming winter, are presented in the present issue. *p. 880–2*

HOUSE telephone cables for large buildings require consideration of many factors to insure that the telephone plant shall be used with the maximum degree of efficiency. *p. 867–9*

# Recommended Practises for the Protection of Electrical Apparatus

**The relay subcommittee of the A.I.E.E. protective devices committee herewith submits its recommendations for the protection of electrical apparatus. These recommendations are based upon a questionnaire and the 37 replies thereto from specialists in this field. Answers were interpreted and codified by a group of 20 experienced engineers particularly interested in the protection of electrical apparatus and circuits. It is hoped that this concensus of present-day opinion will be the beginning of a series that will be augmented and improved with each periodic analysis and reissue.**

IN THE PAST, 3 papers entitled "Transmission Line Relay Protection" have been presented before the Institute. These indicated the progress of the protection art and discussed in some detail certain methods considered general practise at the time they were written. The last one, presented in 1930, contained brief notes on the protection of some of the major items of system equipment. At that time, however, it was believed desirable to have a similar paper prepared, which would be devoted to apparatus protection. It is therefore the purpose of this report to present a review of those methods that are in general favor at the present time, and that are considered good practise for the protection of the main items of electrical apparatus.

Information upon which this report is based was furnished by representative engineers associated with protective problems in public utility and industrial fields. In order that the survey might be as comprehensive as possible, 61 copies of a questionnaire were distributed, of which 35 were returned. To guard against answers being given in the light of past practise the transmittal letter emphasized particularly the value of opinions based upon future applications rather than upon existing installations. Therefore it may be assumed confidently that the condensed results given express the most advanced ideas of a preponderant body of engineers engaged directly in the study of protection problems.

In but few cases the average opinion expressed in the questionnaires differs from the views of the committee. Where such disagreements occur, both opinions are given, together with the reasons that influenced the committee in qualifying the average opinion disclosed by the questionnaire. While agreement was not always unanimous, no radically different views were found to exist.

There appears to be a growing recognition of the importance of considering protection problems from 2 major viewpoints: (1) their monetary significance as insurance against damage to equipment, and (2) the less tangible, but no less vital relation they bear to the value of the service in terms of good-will. The former may be computed readily from existing records of repair costs; the latter is more difficult to evaluate in a pecuniary sense and consequently is susceptible to a variety of conclusions when considered from the angle of return on capital invested. It is not disputed that this return is large, especially in comparison with the cost of the protective devices, and that it probably will loom still larger as power system growth and interconnections continue.

In arriving at the opinions expressed the committee duly weighed the cost of the protective equipment against the value of the results to be expected. This procedure will be found borne out by the kilovolt-ampere ratings for which the more expensive methods of protection are recommended. Not only is a large piece of apparatus inherently more costly than a small one, but its incapacity to operate will result in relatively greater inconvenience to the system it serves.

It should be remembered also that these recommended ratings apply to the general case and that special situations will arise in which it may be

---

Full text of a report (A.I.E.E. Paper No. 33-1) prepared by the relay subcommittee of the protective devices committee to be presented at the A.I.E.E. winter convention, New York, N. Y., Jan. 23–27, 1933.

Members of relay subcommittee—O. C. Traver, *chairman*, Genl. Elec. Co., Phila., Pa.; E. H. Bancker, Genl. Elec. Co., Schenectady, N. Y.; D. L. Bement, Northern Ind. Pub. Serv. Co., Hammond, Ind.; H. D. Braley, N. Y. Edison Co., New York, N. Y.; R. E. Cordray, Genl. Elec. Co., Phila., Pa.; G. B. Dodds, Duquesne Lt. Co., Pittsburgh, Pa.; W. W. Edson, Edison Elec. Illum. Co., Boston, Mass.; L. E. Frost, Bklyn. Edison Co., Bklyn., N. Y.; D. E. George, Tenn. Elec. Pwr. Co., Chattanooga, Tenn.; S. L. Goldsborough, Westinghouse E. & M. Co., Newark, N. J.; W. A. Lewis, Westinghouse E. & M. Co., Pittsburgh, Pa.; H. A. McLaughlin, Central Hudson Gas & Elec. Co., Poughkeepsie, N. Y.; J. H. Neher, Phila. Elec. Co., Phila., Pa.; R. E. Pierce, Elec. Bond & Share Co., New York, N. Y.; C. F. Powers, New England Pwr. Corp., Boston, Mass.; H. M. Rankin, Metropolitan Edison Co., Reading, Pa.; A. W. Rauth, Consumers Pwr. Co., Jackson, Mich.; F. O. Schnure, Bethlehem Steel Co., Sparrows Point, Md.; H. P. Sleeper, Pub. Serv. Elec. & Gas Co., Newark, N. J.; E. R. Stauffacher, So. Calif. Edison Co., Los Angeles, Calif.; George Steeb, Buffalo Niagara & Eastern Pwr. Corp., Buffalo, N. Y.; and E. M. Wood, Hydro Elec. Pwr. Comm., Toronto, Canada.

Others who supplied data through their replies to the questionnaire—T. J. Bostwick, Aluminum Corp. of America, Pittsburgh, Pa.; E. A. Childerhose, Stone & Webster Co., Boston, Mass.; H. W. Collins, Detroit Edison Co., Detroit, Mich.; L. E. Cook, Texas Pwr. & Lt. Co., Dallas, Tex.; A. C. Cummins, Carnegie Steel Co., Duquesne, Pa.; C. H. Frier, Okla. Gas Co., Okla. City, Okla.; G. W. Gerrell, Union Elec. Lt. & Pwr. Co., St. Louis, Mo.; A. S. Goodrich, Hammermill Paper Co., Erie, Pa.; H. H. Green, Pa. Pwr. & Lt. Co., Hazleton, Pa.; J. Hellenthal, Puget Sound Pwr. & Lt. Co., Seattle, Wash.; A. V. Joslin, Pacific Gas & Elec. Co., San Francisco, Calif.; J. T. Logan, Georgia Pwr. Co., Atlanta, Ga.; C. A. Muller, American Gas & Elec. Co., New York, N. Y.; P. H. Robinson, Houston Ltg. Co., Houston, Tex.; J. J. Samson, Commonwealth Edison Co., Chicago, Ill.; C. J. Smith, Illinois Steel Co., Chicago, Ill.; and E. B. Wagner, Lehigh Valley Coal Co., Wilkes-Barre, Pa.

deemed advisable either to raise or to lower them. Machines of a certain rating may seem small on a large system and yet attain considerable importance when the system to which they are attached is itself small. In view of the difficulty of basing recommended ratings upon the size of the system the committee felt that it was preferable to consider such ratings upon the more definite basis of intrinsic values and relative costs of protection.

This report deals particularly with protection against electrical and mechanical failure. When applied to unattended apparatus it overlaps to some extent the field of A.I.E.E. STANDARDS NO. 26 on automatic stations which embrace protection against control failure.

## A-C GENERATORS

*Differential Protection.* In general differential protection is recommended for a-c generators. Equipment used for this protection should disconnect the line and field simultaneously and also the neutral if an adequate circuit breaker is provided. In some cases it shuts down the prime mover. This equipment also should prevent any dangerous rise of exciter voltage when the exciter is connected directly to a hydroelectric generator, or in any other situation in which the exciter may attain excessive speed upon loss of load on the prime mover. As a further precaution against the spread of destructive effects following an internal failure, the differential relay may be utilized to liberate carbon dioxide within the shell of any machine that has a degree of enclosure sufficient to render the gas effective.

For generators of either the open or enclosed type at attended stations differential protection is recommended for ratings of 1,000 kva and higher. The average, as derived from answers to the questionnaire, is 3,000 kva; but in view of the intrinsic value and the good results on record the committee felt justified in lowering this figure. At unattended stations differential protection is recommended for generators rated at 250 kva and higher.

From the standpoint of service, frequently a small generator may be as important as a larger one; this is especially true where a small machine is operating directly on a bus with larger generators which already are provided with differential protection. In such case a fault in the small generator, if not quickly removed, may prove as embarrassing to the service as a similar fault in a large generator; hence here differential protection for the small machine is strongly indicated.

In view of the decreased hazard of insulation failure at low voltages this form of protection is recommended only on machines rated at 2,300 volts and higher. This opinion is strengthened by the high currents usually encountered at lower voltages, since these require rather massive terminals and involve greater difficulty in bringing out all of the necessary armature leads.

It is recommended that the zone protected by the differential relay include as far as possible all conductors that extend from the generator armature to the bus and the circuit breaker as well.

On generators of 20,000 kva or larger, having 2 or more parallel windings per phase and where there is a possibility of turn-to-turn failure, it is recommended that additional protection be provided in the form of a differential relay actuated by a difference of in-phase currents that may occur in the parallel windings. When the neutral is solidly grounded a turn-to-turn fault will develop quickly into a fault to ground; therefore this protection is recommended particularly in cases where the generator neutral is not solidly grounded. The possibility of circulating currents also must be investigated when parallel balance is contemplated; perhaps, however, these can be avoided when the machine is designed. Unless this precaution is taken it is possible that on external faults circulating currents may cause improper operation of the relay. With some types of armature windings this relay also is capable of detecting short-circuited turns in the field winding. Since this form of protection is recommended only for large machines its provision adds but a small fraction to the over-all cost of the unit.

*Overcurrent Protection.* The use of overcurrent protection for generators in attended stations is not regarded favorably, but is recommended for back-up protection at unattended stations. When generators at attended or unattended stations are not provided with differential protection, then overcurrent devices, actuated either directly by the armature current or by its thermal effect as in a replica relay, should be employed. However, because of the rapid decrement of the short-circuit current, care must be exercised in the use of overcurrent relays.

A replica relay operates at a specific temperature of its own mechanism which is designed to have at all times the same temperature as the device protected, when subjected to the same ambient conditions. Other types of temperature relays function on the actual temperature of the machine as determined by elements in direct contact, such as embedded temperature coils or thermocouples. Temperature relays are regarded as a valuable guide to the operator. It is the general opinion that in attended stations they should not disconnect the machine, but should provide only a warning signal.

*Field Temperature Protection.* In general field temperature protection is not recommended. An exception, however, is made in favor of its application to generators that are provided with high speed excitation and paralleled over long transmission lines. Under short-circuit conditions a heavy field is applied quickly to hold these generators in step; if this field current is not reduced within a reasonable time it is possible for the generator field to overheat without the knowledge of the operator. To guard against this contingency a field temperature relay may be provided to sound an alarm in attended stations and to shut down the overheated machine if the station is unattended.

*Power-Directional Protection With Time Delay.* In the past this combination of protective devices occasionally has been used to prevent motoring on the part of a steam-turbine-driven generator. Since the purpose which it served now can be taken care of automatically at the throttle, it is the general opinion that, except perhaps in rare cases, the need for this form of protection no longer exists. Its use as a protective measure against internal insulation failure is not recommended and can be justified only in the case of old machines which are not provided with sufficient armature terminals for the application of differential protection.

*Bearings.* Temperature protection is recommended for the main bearings of all unattended machines.

*Protection Against Overspeed.* It is agreed that the usual provision at the prime mover for protection against overspeed is satisfactory for the purpose and that nothing further should be necessary.

*Protection Against Accidental Loss of Field.* Protection against loss of field is recommended for disconnection of the generator at unattended stations. A d-c undercurrent relay is the logical device for this purpose, but it must be given a suitable time delay to prevent its operation during transients reflected from the armature under short-circuit conditions. In attended stations this type of protection seldom is used; where it is used the relay should not disconnect the generator but may provide an indication to the operator upon the occurrence of this condition.

### FREQUENCY CONVERTERS; SYNCHRONOUS CONDENSERS

Recommendations regarding protective equipment for a-c generators apply also to frequency converters and synchronous condensers. In addition it is believed that some provision (usually time overcurrent relays) should be made for disconnecting a frequency converter under out-of-step conditions. Usually it is advisable to provide also time-delayed under-voltage protection for synchronous condensers. No distinction is made between attended and unattended stations in the use of these additional features.

### D-C GENERATORS

At attended stations protection against overcurrent is considered necessary for d-c generators and, in addition, when these machines operate in parallel with another source of power, provision should be made for protection against reversal of the normal direction of current flow, functioning independently. Additional refinements are usually necessary in unattended stations, but the variety and special nature of these devices do not permit of their inclusion in a general condensed report. They may be found listed in A.I.E.E. STANDARDS NO. 26.

*Bearings.* Temperature protection is recommended for the main bearings of all unattended machines.

*Exciters.* When exciters are direct-connected and do not operate in parallel, it is recommended that no protection against electrical failure be used. For parallel operation, protection against overcurrent in a reverse direction should be provided. The current setting should be high enough to prevent possible disconnection of the machines when paralleling and when momentary disturbances are reflected from the a-c generator armature during a-c short circuits.

### POWER TRANSFORMERS AND POWER AUTO-TRANSFORMERS

*Differential Percentage.* When circuit breakers are provided for each winding, percentage differential protection is recommended for 2- or 3-winding power transformers of 1,000-kva rating and higher, either with or without tap-changing equipment, and whether operated singly or in parallel. As disclosed by the questionnaire the average minimum rating for which differential protection is recommended was found to be 5,000 kva. The committee recommends that differential protection always be provided for banks of 5,000 kva and more if operated in parallel, even though additional breakers must be purchased. When the transformer bank is part of a line and is provided with a circuit breaker on the bus side only, certain modifications of the foregoing method are recommended. These will be found under a subsequent heading.

When the necessary circuit breakers are provided for complete isolation of a power auto-transformer, percentage differential protection is recommended for an equivalent physical capacity of 1,000 kva and greater. It is recommended also that all banks of power auto-transformers operated in parallel of an equivalent physical capacity of 5,000 kva and greater be provided with differential protection even though additional breakers must be purchased. The auto-transformer output rating corresponding to 1,000 or 5,000 kva of equivalent physical capacity will vary, of course, with the ratio of voltage transformation. In general the ratio of the equivalent physical capacity of an auto-transformer to its output is equal to the per cent voltage transformation, based upon the high voltage thus:

$$\frac{\text{Equivalent capacity}}{\text{Rated output}} = \frac{E_1 - E_2}{E_1} = 1 - \frac{E_2}{E_1}$$

where $E_1$ is the high voltage, and $E_2$ the low voltage.

It is recommended that circuits embraced by the differential protection include all conductors up to and including the circuit breakers on each side of the transformer.

*Overcurrent Percentage (Differentially-Connected).* When differentially-connected overcurrent relays are used in place of percentage differential protection for any of the foregoing types of transformers, it is recommended that they be of the inverse time type. This time characteristic prevents operation on external faults which otherwise may create sufficient unbalance at the relay to bring about needless tripping.

*Back-Up Protection.* In addition to differential protection, overcurrent or other back-up protection (not necessarily at the transformer itself) should be provided at some point on the source side to protect the transformer against the effects of sustained excess currents which may arise from failure of protective apparatus to clear faulty equipment. Temperature relays, either operated by embedded coils or of the replica type (described under "A-C Generator Over-Current Protection"), also occasionally are employed. When a transformer is not protected by differential methods it is recommended that overcurrent protection always be provided.

*Smoke or Gas Detectors.* Insufficient experience with these devices in the United States precludes the expression of an opinion regarding their value, or their possibilities, as a means of transformer protection.

*Transformers Having Breakers Only in the Low Side.* Power transformers that have a circuit breaker on the bus side only, the other side being connected directly to the line, generally are treated as part of the line and consequently included in the line protection. When the latter is protected by distance or directional overcurrent relays it is suggested that differential protection also be considered for the power transformer and that this protection be arranged to trip the transformer breaker. Under some circumstances this will result in speedier isolation of the disturbance. For example, if a fault occurs in the transformer during a period when normal power is flowing from the bus toward the far end of the line, the directional relay at the distant end cannot respond to the fault current until it has grown to proportions sufficient to overcome the torque produced by the normal direction of power. By quickly tripping the bus breaker, however, the differential relay interrupts the normal flow of power and thus frees the distant directional relay of its normal power torque. The directional relay then responds to the feeble fault current and the transformer is isolated before serious damage can result.

*Magnetizing Transients.* Replies to the questionnaire disclose that trouble from magnetizing transients is of sufficiently frequent occurrence to warrant some statement by the committee regarding means for overcoming its effect on the protective relays. Inrush magnetizing currents disturb the balance at the differential relay, and may cause needless tripping of the breakers. The ability of power sources of large capacity to maintain full voltage at the inception of the transient adds greatly to the magnitude which it may attain. These abnormal currents are caused primarily by the residual magnetic flux; should this be of appreciable magnitude, and in a direction such that the flux change required by the voltage at the moment of switch closure will push the total flux above the knee of the saturation curve, it follows that the magnetizing current will be unduly large. The difficulty is more pronounced on 25-cycle systems.

Special or additional equipment is available for preventing tripping during the magnetizing transient and this precaution is always necessary when high speed relays are used. The more common types of relays, however, being slower, usually will ride safely through the transient; where such relays are employed the committee believes that the addition of the special equipment referred to should be based more properly upon the trouble which the user encounters.

It is pointed out also that undesired operation of differential relays may occur at the moment of clearing an external fault originating in the vicinity of the transformer. Just before the fault is cleared the voltage at the transformer may have fallen to 0 and immediately afterward will tend to return to normal, thus simulating on a smaller scale the conditions obtaining at initial magnetization. Experience with trouble arising from this cause having been meager, the committee does not feel called upon to suggest measures for its avoidance.

## A-C MOTORS

An analysis of the replies to the questionnaire indicates a general agreement on the desirability of differential protection for large a-c motors, the average minimum rating at which it should be applied being 1,750 hp. It was the opinion of the committee that motors of 2,000 hp and more, with a minimum rating of 2,200 volts, should be provided with differential protection.

*Overcurrent Protection.* In addition to differential protection, temperature relays, either of the replica type or operated by embedded coils, are recommended for protection against excessive or prolonged overloads. Due to loss of cooling by windage the latter will represent more accurately the true motor temperature under stalled-rotor conditions.

For motors of less than 2,000-hp rating where differential protection is not employed inverse time overcurrent and instantaneous overcurrent protection is recommended, the instantaneous relay being set for currents greater than the stalled-rotor current to take care of severe short circuits only.

*Undervoltage Protection.* When undervoltage protection is used it should have sufficient *time delay* to enable the motor to coast through temporary dips in voltage. Undervoltage protection is not recommended for motors that start on full voltage since these will come up to speed automatically when normal voltage is resumed.

*Phase-Rotation Protection.* Relays to guard against reversal of phase-rotation are recommended chiefly for use at unattended stations and in elevator service.

*Protection Against Unbalanced Phase Currents.* Dielectric failure results in unbalanced phase currents and negative phase-sequence components. This condition may be detected by a relay which is actuated either by the unbalanced phase currents themselves or by their corresponding negative phase-sequence components. When differential protection is not possible or practicable these relays frequently are used at unattended stations; but it should be remembered that phase-balancing action will produce unbalanced conditions in sound motors and thus may lead to erroneous tripping of circuit breakers on the occasion of an external unbalanced fault.

*Bearings.* Temperature protection is recommended for the main bearings of all unattended machines.

*Power Station Essential Auxiliary Motors.* It is important that motors driving essential power station auxiliaries not be removed from service except as a last resort and then, in the interest of service, their isolation should be accomplished as promptly as possible. For this reason it is recommended that such motors be protected by instantaneous overcurrent relays set for currents considerably greater than the stalled-rotor current. When temperature relays are used in connection with these motors they should be arranged to sound an alarm only. Phase-balance relays or negative phase-sequence relays are not recommended for essential motors because of the phase-balancing tendency of polyphase motors mentioned in the second preceding paragraph.

It is not common practise to ground the neutral of the supply source for essential motors, but if for any reason such a condition exists, ground relays advantageously may be added to the protection.

### D-C Motors

Fuses are considered sufficient protection for small d-c motors. For medium and large sizes overcurrent and undervoltage protection, usually self-contained in the air circuit breaker itself, are recommended. Where the machine is very large, and its service correspondingly important, additional refinement in the form of temperature protection is desirable.

*Bearings.* Temperature protection is recommended for the main bearings of all unattended machines.

### Synchronous Converters

Synchronous converters require protection on both the a-c and the d-c sides. On the a-c side inverse-time overcurrent protection is recommended to trip the oil circuit breaker. In addition, when the d-c side is grounded and flashover possible, an instantaneous flashover relay, connected between the machine frame and ground, is recommended to disconnect both the a-c and d-c sides. If the possibility of flashover exists, and no flashover relay is provided, it is recommended that the overcurrent protection on the a-c side be instantaneous instead of inverse time. For the d-c side instantaneous overcurrent protection is recommended, and in addition, when the machines are operated in parallel, separate reverse current protection should be provided to disconnect the converter when power flows toward it from the d-c bus. Most synchronous converters are equipped with mechanical overspeed devices; these should trip the d-c circuit breaker and, if the system is subject to runaway speeds, the a-c circuit breaker also. Additional information will be found listed in the A.I.E.E. Standards No. 26 on Automatic Stations.

*Bearings.* Temperature protection is recommended for the main bearings of all unattended machines.

### Rectifiers

Rectifiers are almost universally automatic in their operation. It is believed that recommendations for their protection are covered adequately by the tabulation given in A.I.E.E. Standards No. 26 on automatic stations.

### Bus Protection

*Differential.* All failures occurring on important buses should be promptly isolated. Differential methods which balance all currents entering and leaving the bus are recommended for this purpose. In such applications it is important that the ratio characteristics of the current transformers in the differential circuit should hold substantially within the relay setting at the maximum primary currents so that incorrect operation cannot occur on external faults. With a given core design the higher the transformation ratio the more accurate is the ratio curve. Desired conditions can be achieved best by the use of a single ratio for all current transformers taking part in the differential scheme. If it is not possible to follow this recommendation and current transformers of different ratios are employed, then auxiliary current transformers must be used in the secondary circuits to equalize the different ratios at the balance point.

It should be noted, however, that when an auxiliary transformer is used to increase the ratio of a low-ratio line current transformer, a double handicap is placed upon the equipment compared to that which would result from the use of a single current transformer having the same total ratio. This follows because: (1) In the lower-ratio transformer ratio-error begins at lower currents; and (2) the additional burden imposed by the auxiliary transformer also has the effect of increasing the ratio-error in the line current transformer.

Under certain conditions of power feed restraint may be used advantageously in the differential relay. In general, however, these conditions do not obtain and the effect of restraint if used cannot be predicted with any degree of certainty.

*Ground Fault Bus.* When the system is grounded a ground fault bus may be used, each protective relay being operated by a current transformer inserted in the common ground connection for its particular bus section. If provision be made for the application of this method during the station design period, its installation does not involve the serious constructional difficulties that may be encountered in attempting to introduce it in an existing station.

### Grounding Equipment

*Grounding Resistors and Reactors.* It is recommended that grounding resistors and reactors be protected by overcurrent or temperature relays which, after a short delay sufficient to allow line protection to function, will initiate an alarm to indicate that a ground fault has not been cleared properly. This procedure is designed to give the operator an opportunity to carry out a course of action already decided upon for such conditions.

Fortunately the trend toward the use of resistors having a 2-min ground fault capacity allows reasonable time for disconnecting the source of trouble without opening or short-circuiting the resistor. Should either of these latter courses become necessary, however, it would seem preferable from a protection standpoint to maintain the system ground by short-circuiting the resistor, unless this action nullifies the purpose, such as prevention of telephone interference, for which the resistor originally was installed.

*Grounding Transformers.* Protection for grounding transformers of either the zig-zag or Y-Δ type should follow substantially along the lines indicated for grounding resistors and reactors in so far as the effects of sustained external ground faults are concerned.

For protection against internal faults 2 forms of differential protection may be used. In one of these, 3 differentially-connected overcurrent relays are operated in Y from the Δ-connected secondaries of 3 current transformers in the line side of the grounding transformers. This is equivalent to differential protection on an ordinary transformer at times when no load is being carried by the secondary, since in the grounding transformer the secondary Δ winding carries no external load; it provides protection against both turn-to-turn short-circuit and internal grounds occurring in the transformer or on the conductors between the transformer and the current transformers. The other method compares the zero phase-sequence currents on both sides of the grounding transformer by means of 3 line current transformers connected in parallel and balanced against a current transformer connected in the neutral. Since turn-to-turn faults do not result in zero phase-sequence currents this method does not protect against such faults but functions on faults to ground only. In applying these forms of protection it is important that the characteristics of the operating current transformers be checked up to maximum short-circuit values.

IMPRESSIONS

In looking over the preceding recommendations one cannot fail to be impressed by the prominent place still occupied by the simple overcurrent relay in the protection of a wide range of electrical apparatus. Even where it has been supplanted in the first line of defense by more highly selective devices, it still is relied upon as a safeguard of last resort. Nor is this surprising when it is remembered that in any analysis of the destructive effect of dielectric rupture, the major damage is brought about by the thermal or magnetic effects of *high currents.* This thought tends to strengthen the belief that the persistence of the overcurrent relay as an important protective agent is destined to extend well into the future.

Growing interconnections have brought increasing problems to the operating engineer, and his demand for the rapid isolation of faults has brought similar problems to the relay designer. In recent years the trend has been toward the attainment of greater operating speeds with increased selectivity. However, progress in fields other than that of the relay also is to be recorded: Current transformers offering uniform characteristics up to exceptionally high currents are now on the way, and circuit breakers capable of interrupting these currents in a brief period of time already have been developed.

No discussion on protective methods can be complete without some reference to the primary position of the insulation itself. That improvements have been effected in apparatus insulation during recent years cannot be questioned; but there are quite obvious economic factors limiting the extension of the insulation to a point of absolute dependability under any and all conditions. Direct lightning strokes still are to be feared and the dangers from them cannot be overcome economically by increased insulation. Beyond the point at which greater insulation becomes impracticable the relay always must find its place in the protective economy of the electrical system.

# Safe Harbor-Westport

## 230-Kv Transmission Line

**Designed according to the latest ideas concerning lightning protection, the Safe Harbor-Westport 230-kv line is said to be the most heavily insulated so far constructed. Ground wire protection has been applied according to the latest theory, and special effort has been made to reduce tower to ground resistances.**

RELIABILITY of transmission has been a matter of foremost importance in the design and construction of the 230-kv line connecting the Safe Harbor hydroelectric plant with the Westport steam station in Baltimore. This has been so not only because a large portion of the ultimate capacity (510,000 hp) of the Safe Harbor plant will be available for Baltimore, but also because during certain periods Baltimore will be dependent primarily upon Safe Harbor power.

Selection of high operating voltage was made only after a thorough investigation of (1) the relative economics and reliability factors involved, (2) the possibility of future interconnections, and (3) system stability. Studies made jointly with engineers of the Consolidated Gas, Electric Light and Power Company covered a comparison of 2 230-kv circuits with 6 110-kv circuits. These studies included also investigation of such problems as terminal location, 2-point versus single-point supply, the use or omission

---

Based upon "Safe Harbor-Westport 230-Kv Transmission Line" (No. 32M16) presented at the A.I.E.E. Middle Eastern District meeting, Baltimore, Md., Oct. 10-13, 1932.

of high voltage buses, and amount of synchronous condenser capacity required. An a-c calculating board was employed to check the results obtained by analytical methods. The decision finally was made in favor of the higher voltage as offering lower cost, greater reliability, and greater possibilities for interconnection.

### ROUTING OF LINE

Voltage regulation on the network in Baltimore, and control of short-circuit currents made advisable the delivery of power to each side of the city. As shown in Fig. 2, the present line circles the city and enters from the south; the second line as projected will terminate to the east of the city near the site of a future steam station. Routes for the 2 lines diverge on leaving the Susquehanna River and are so widely separated that the possibility of a lightning storm affecting both circuits simultaneously is almost non-existent. At present, Westport is the center of distribution in Baltimore; therefore, the termination of the line at this point called for less additional investment in distribution facilities.

Most of the terrain traversed by the line is rather rugged, and about 23 of the 70 miles is wooded. As the country is thickly settled, wire and railroad crossings are frequent. These include 4 66-kv and 12 railroad crossings, all of which increased the cost of wire stringing. The right-of-way is 150 ft wide and consists of part easements and part fee simple.

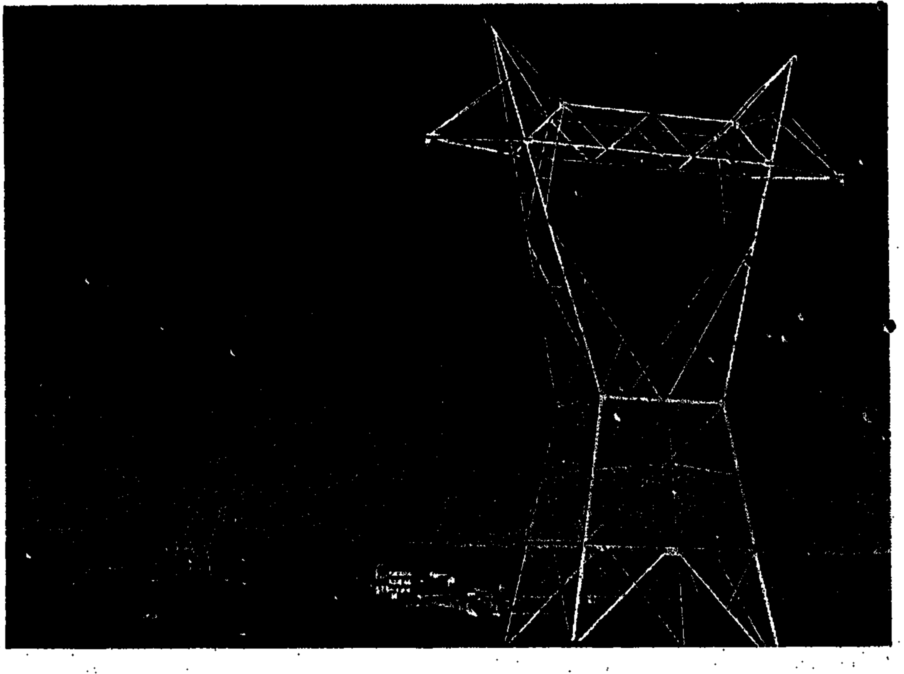

Fig. 1. A section of the line showing a type A tower in the foreground

Actual design and construction of the line were preceded of course by the usual preliminary surveys and detailed engineering studies. Lightning being considered the worst enemy of transmission lines in this part of the country, special design features were incorporated to minimize troubles from that source; these features include increased insulation, 20 10-in. suspension units with 5-in. spacing, and ground wires installed in accordance with the best design information available.

After the approximate location had been determined, and before the actual surveying of the property had begun, the route was photographed from the air, and the final route was laid out on a mosaic made to a scale of 1,000 ft per in. Later a profile was plotted from the United States Geological Survey map, from which the average span length and height of tower were determined. Final specifications were so drawn that the designers were not limited to any particular type of tower as designs submitted by manufacturers varied greatly in appearance and weight. A final selection was made from the various designs after a comparison on the basis of towers erected in the field. Details of some of the more interesting features of the line are given in the paragraphs that follow.

### TOWERS

Originally 3 types of towers were used as a basis for design: type A for straight line and angles up to 3°; type B for angles from 3° to 15°; and type C for angles over 15° and for dead ends. Type A was modified to meet railroad specifications, the modified form being designated as type E. Later a transposition tower was brought out as type D.

As shown in Figs. 1 and 3, the towers are of the waist line type. (See "Load Test Check Tower Designs," by R. W. Wilbraham, *Electrical World*, Nov. 12, 1927.) This design gives the lowest footing reactions and by the use of body extensions permits variations in the length of leg with a minimum number of pieces. Sags and cable tensions were computed on the basis of N.E.L.A. heavy loading. In determining tower loadings one broken conductor

at a tension of 10,000 lb was assumed for "A" towers; dead end towers were assumed to have 3 broken conductors and 2 broken ground wires stressed to the elastic limit. All fittings are designed for a vertical load corresponding to one inch of ice on the conductors. Table I gives allowable stresses for design loadings. For test purposes all design loads were increased 25 per cent. Weights of the towers are shown in Table II.

Phase separation and length of crossarm were determined from the clearance diagram shown in Fig. 4. The ground wires were located so as to give maximum protection against a direct lightning stroke. Originally only 2 transpositions were contemplated. A third, however, was added at the request of another utility company. The original transpositions are somewhat unusual in that only 2 conductors are transposed at each point. This is sufficient to balance the conductors against each other but does not balance them against outside exposures; the transposition requested by the other utility was for this latter purpose and had to be complete. It was made by placing 2 transposition towers consecutively in the line.

For all but dead-end towers concrete foundations of the inverted mushroom type are used; these are designed for 100 per cent overload. This type of foundation can be built as cheaply as the grillage type; also it makes possible much closer alinement, resulting in a considerable saving in cost of erecting towers. Foundations for dead-end towers consist of angle iron stubs carried down to the bottom of the excavation and set in concrete. The average amount of concrete required for line towers is 4 cu yd; for dead-end towers 25 cu yd.

## Conductors and Ground Wires

Before the final selection was made several types and makes of conductors were investigated, and their effects on spacing and height of towers studied. After comparing the various designs, a 795,000-cir mil A.C.S.R. (aluminum cable steel reinforced) conductor was chosen. The most advantageous combination of other metals considered would have required towers 5 ft higher than those designed for use with the conductor selected, would have been considerably higher in cost, and did not offer sufficient advantage to offset this difference in cost. Physical characteristics of conductors and ground wires are shown in Table III.

Conductor and ground wire tensions were held low (see Table III) in order to guard against vibration troubles. In addition, armor rods were provided at all suspension clamps. Sags and tensions were calculated from actual stress-strain curves as determined on tested samples 50 ft in length. During normal conditions, the sag of the ground wire is 5 ft less than that of the conductor. When loaded with $^1/_2$-in. of ice, these wires will parallel the unloaded conductors. Sags were adjusted without prestretching and are somewhat less now than they will be after being subjected to an ice load.

No effort was made to secure any special slip features in the suspension clamps as the J-bolts automatically limit the pressure on the conductor. Armor rods are secured by ovoid clamps which do not present any points or sharp edges to start corona streamers. Compression type clamps are used for all dead-ends and splices, the steel and aluminum being held separately. Dead-end towers are bridged by underslung bolted jumpers.

## Insulators

Insulators at all suspension points are standard 10-in. suspension disks with 5-in. spacing. Suspension strings consist of 20 units and are doubled at all points where the load exceeds 4,500 lb. Clearances are provided for grading rings but none is used at the present time. On all dead-end towers double strings consisting of 20 10-in. 25,000-lb strength insulators with 5$^3/_4$-in. spacing are used.

## GROUNDING

Ground wire protection is based upon a tower footing resistance of 50 ohms or less. A field check, however, showed that footing resistances varied from 1 ohm to 400 ohms with an average of 79 ohms; only 6 of the 351 towers had footing resistances below the 50-ohm limit.

Several different methods for reducing the ground resistance were investigated and some of them tested in the field. The method finally adopted as being most effective employs a 50-ft wire extending out radially from each corner of the tower, and buried about 20 in. below the surface of the ground. Each of these wires terminates in a salt treated grounding rod. The average resistance to ground of 4 wires and rods is 34 ohms. In a few cases the addition of these wires was insufficient to reduce the combined resistance to 50 ohms. Adding more wires in such cases proved rather disappointing, however, as the additional reduction amounted to only 10 or 15 per cent.

In order to determine the comparative effectiveness of a longitudinal counterpoise, about 4$^1/_2$ miles of $^3/_8$-in. copperweld wire was buried along a section of line. As far as low frequency resistance is concerned, this proved less effective than 4 radial wires, and is more costly.

## SPECIAL FEATURES

Both the present and the proposed 220-kv lines to Baltimore are brought out from the upstream face of the power house, across the forebay to a hill on the east shore of the river. This hill will be the site of a future high-voltage switching station. On top of the hill the lines swing around to a river crossing on the downstream side of the power house. The distance across the river at this point is 5,725 ft. An island situated in mid-stream is used as a tower site and the crossing made in 2 spans of 2,880 and 2,845 ft, respectively. The hills on either side of the river are at el 500 and 450, while bed rock on the island is found at el 170.

High water in the river will reach el 190; hence any tower placed on the island must be set above this elevation to protect it against water and ice. Accordingly, the tower piers have been made heavy enough to withstand the maximum load expected from ice and water. To avoid building 2 sets of such piers, it was decided to place both circuits on one tower; this tower is 183 ft high, and has a spread at the base of 75 ft and a crossarm 146 ft long. The steel structure is carried down to bed rock where it is anchored with 24 2-in. bolts sunk 9 ft in the rock. The lower 25 ft of the tower legs are encased in concrete. The total weight of the tower is 180,000 lb.

Conductors in the crossing are 803,000 cir mils A.C.S.R. strung to a tension of 7,500 lb, and the ground wires 286,000 cir mils A.C.S.R. strung to a tension of 5,650 lb. Maximum tensions are 17,565 and 13,380 lb, respectively.

The problem of stringing this crossing presented some difficulties. The island was too narrow for a "reel set up" and therefore the cables had to be pulled from the shore to the island. Motive power was furnished by an electric power winch. The river bed at this point is full of submerged rocks so that the cables had to be kept above the water surface to guard them against injuries. The tension required to keep the cable from sagging down into the water however made it extremely difficult to pull the cable out. The problem was solved by stringing a $^5/_8$-in. steel messenger cable and trolleying the conductors over on the messenger.

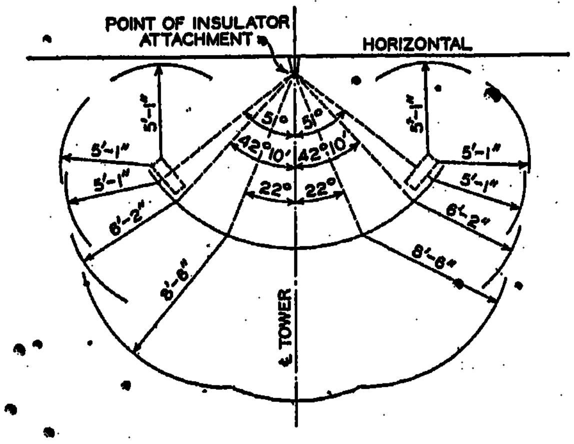

Fig. 4. Clearance diagram for type A tower

**Table III—Characteristics of Conductors and Ground Wires**

| | Conductor | Ground Wires |
|---|---|---|
| Size A.C.S.R. | 795,000 cir mils | 203,200 cir mils |
| Per cent steel | 39.5 | 71.9 |
| Stranding | 30x0.1628-in. al.<br>19x0.0977-in. steel | 16x0.1127-in. al.<br>19x0.0977-in. steel |
| Diameter | 1.140 in. | 0.714 in. |
| Weight per foot | 1.234 lb | 0.6785 lb |
| Ultimate strength | 37,770 lb | 26,600 lb |
| Elastic limit | 27,250 lb | 18,620 lb |
| Tension at assumed maximum load (1/2-in. ice, 8-lb wind, 0° F) | 12,000 lb | 9,060 lb |
| Tension at 60° F | 6,175 lb | 4,180 lb |

The line was built during a period of low material

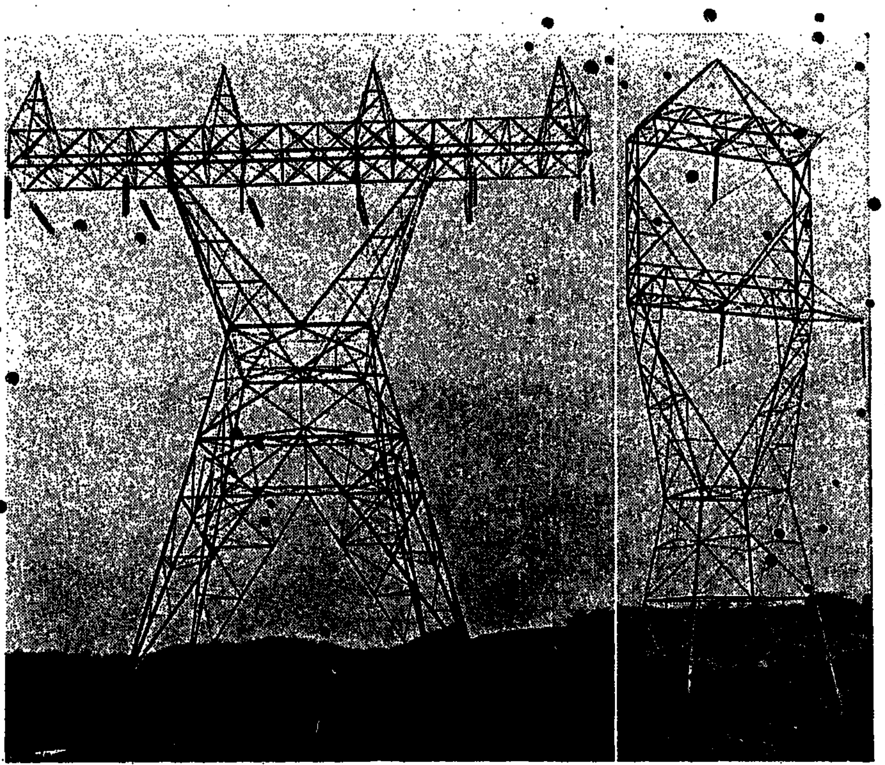

Fig. 5. (Right) Type D transposition tower

Fig. 6. (Left) Double circuit river crossing tower on island just below the Safe Harbor plant prices and plentiful supply of labor. The right-of-way department kept well ahead of construction so that work, when once started, proceeded without delay. Actual field work began March 1, 1931, and the line was turned over to the operating department December 4, 1931, 9 months and 4 days after the work was initiated. Mechanical equipment kept the organization small (150 men maximum) and helped to speed up the work.

Much has been said about the frailty of A.C.S.R. and about the precautions needed to protect it against damage. The Safe Harbor-Westport line was strung without any special safeguards, yet it stands completed with only 3 repair sleeves, 2 of which could have been left off. In addition to these, about 150 ft of cable had to be cut out because of damage when a conductor jammed in a roller block which had not been closed properly.

# Pulp Insulation for Telephone Cables

After some 40 years of service spirally wrapped paper insulation is rapidly being displaced for interoffice and subscriber loop cables, by a pulp insulation applied directly to the conductor by a process which brings the paper mill into the cable plant and combines the paper making and insulating operations into one process with the elimination of a number of costly intermediate steps. In addition, this process makes possible the use of a less expensive material as an insulating medium.

INSULATED wire of a type considerably cheaper than paper ribbon insulation has been developed. The insulation is formed from paper pulp directly on the conductor by a special type of paper-making equipment. This equipment is not critical to the kind of pulp used but for the purposes of durability, strength, and economy a Kraft wood pulp has been used in telephone cables. The process has progressed through the development stage and is now in continuous operation in the commercial production of all the principal exchange area cables of 24 and 26 A.W.G. conductors used in the Bell system. (Fig. 2.) Thousands of miles of lead-encased pulp insulated cables, ranging in size from the smallest consisting of 11 pairs to the largest consisting of 1,818 pairs, are now giving satisfactory service and because of the substantial economies which the construction promises for the finer wire cables, attention is being directed toward its possible application to larger gage cable conductors and to its use as an insulating medium for other electrical circuits.

For many years conductors for lead-sheathed telephone cables were insulated by helically wound strips of paper made from a stock composed of all old rope, or old rope and a small admixture of cotton. In an effort to find a suitable less expensive fiber, however, a formula composed of about 40 per cent chemical wood pulp and the remainder rope stock was adopted in 1920 for the larger sizes of paper only. This wood fiber is of the spruce or other coniferous tree species prepared by the sulfate or Kraft process. Extensive tests have demonstrated that it compares favorably in stability and permanence with the well-established manila fiber. In the case of the newly developed pulp insulated cable, the raw material used is 100 per cent Kraft wood fiber.

Work was initiated in 1921 to determine the possibilities of producing a continuous homogeneous paper covering directly on the wire. Preliminary tests were sufficiently interesting to warrant proceeding further with the project. A 10-wire machine was started up in 1924, with very indifferent success, but succeeding developments in technique and improvements in equipment resulted in a product so satisfactory that the machine was expanded to a 50-wire capacity and put in operation early in 1928. In 1931, 10 more wires were added. The product was cabled into 26 and 24 A.W.G. cables on standard cabling equipment with no major difficulties, and installed in commercial telephone plant by

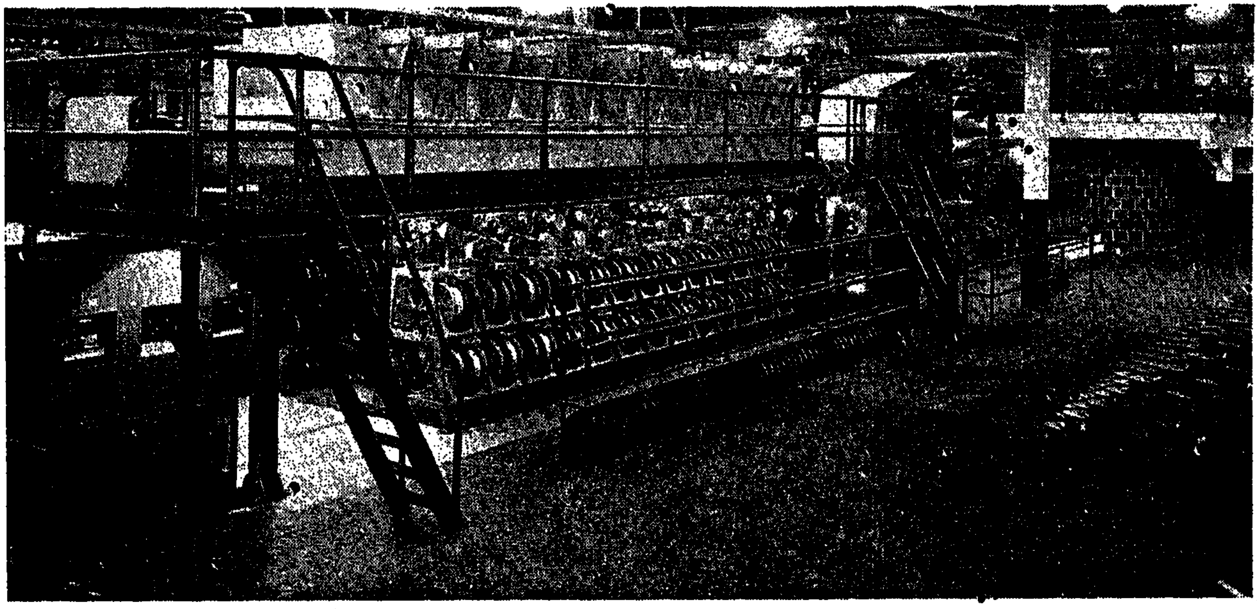

Fig. 2. General view of pulp insulating equipment. The take-up and dryer are shown in the left foreground; the polishers and wet machine in the right center; and the wire supply and pulp preparation equipment in the right background

the operating companies. No serious operating trouble has developed in any of this cable.

The pulp insulated wire capacity now at the Hawthorne and Kearny plants is approximately 225,000,000 conductor feet per week and all 24 and 26 A.W.G. exchange area cables are being manufactured from pulp insulated wire.

## PROCESS OF MANUFACTURE

The insulating material which is to be placed on the wire is given practically the same treatment in a beater as it would receive in paper making, but without the addition of sizing or loading. The beaten pulp is stored in a large tank from which it is pumped to a mix box for dilution with water before passing to the screen where coarse particles and lumps are removed. (Fig. 1.)

For the next operation a modified paper machine of the cylinder type is used. The mixture of pulp and water is fed into the cylinder vat by gravity from the screen. The cylinder mold itself is divided into 60 narrow uniform sections by dams or deckles on the surface of the wire cloth covering. The bare conductors coming to the machine are guided so that one conductor passes around the mold in each of the sections. As the mold is rotated in the water suspension of pulp in the vat, a narrow continuous sheet of paper with a conductor embedded in it is formed in each section by the simple paper making process of straining the fibers from the suspension as the water flows through the fine wire cloth covering the mold, under the slight head maintained outside the mold. These sheets are transferred from the mold to a woolen felt by the pressure of a couch roll and carried by it through 2 presses which take out a considerable part of the water and leave the material in shape to be turned down to the final form. This is done by passing the conductors embedded in the narrow sheets through individual polishers which turn the wet sheet down into a uniform covering of a size determined to a large extent by the amount of pulp deposited in the sheet. These polishers are simply rapidly rotating heads carrying 3 specially shaped blades so arranged that 1 blade deflects the traveling wire and sheet from a straight line against the other 2, with a pressure controlled by the tension on the wire.

Table I—Approximate Fiber Concentrations

| Step in Manufacture | Per Cent | Step in Manufacture | Per Cent |
|---|---|---|---|
| Beater | 3.5-4 | Cylinder vat | 0.05 |
| Storage | 1.3 | Polishers | 28 |
| Screen | 0.07 | Completed insulation | 91 |
| | | Finished cable | 100 |

The wet cylindrical insulation is then dried to about a 9 per cent moisture content by a single passage through a horizontal electric furnace 26 ft long, the wet end of which is maintained at a temperature of about 1,500 deg F and the dry or tempering end at something under 800 deg F. The wires are carried through the drier by a rotary pulling mechanism designed to minimize the crushing or flattening of the dried insulation. This device delivers the finished product to the take-ups for spooling. The machine is operated at about 130 ft per min.

Considerable amounts of water are used in the process, for in this, as in all paper making processes, water acts not only as a carrier for the fibers, but it forms some sort of a loose chemical or mechanical combination with them in the beater and is one of the principal factors in determining the final characteristics of the material. The approximate fiber concentrations at the various steps of manufacture are given in Table I.

In theory the whole process is remarkably simple, but from the practical standpoint many intricate problems had to be solved before satisfactory operation was possible. Means, for example, had to be worked out for shifting from an empty spool of wire to a full one without shutdown or break in conductor or insulation. Also methods of restringing broken wires with the machine in operation had to be developed. Continuous 6-day week operation now is possible without shutdowns except for the mid-week clean-up. The satisfactory working out of many other details also was necessary to secure the present smoothness of operation.

## PHYSICAL CHARACTERISTICS

The physical characteristics of pulp insulation, some of which are shown in Table II, may be modified somewhat by choice of materials and methods of manufacture, but they cannot be controlled entirely. The comments which follow cover only the sizes which have been run almost exclusively to date, namely 24 and 26 A.W.G. wire, but it should be noted that wires ranging in size from 19 to 28 A.W.G. have been covered successfully.

The physical characteristics shown in Table II are controlled by the beating of the pulp, the amount of pulp fed to the machine, the dryness of the sheet in the polishers, and the speed of drying. The tensile strength and flexibility of the insulation can be varied through wide limits by different treatments during manufacture. The elongation is quite comparable to that of ordinary paper and is not susceptible of much variation. The insulation is made sufficiently strong and flexible to withstand the various operations incident to cable fabrication and subsequent handling yet not so tough that it cannot be readily removed from the wire at the point of splicing.

**Table II—Some Physical Characteristics of Pulp Insulation**

| Characteristic | Range of Values Obtainable |
|---|---|
| Diameter of insulated wire—inches | 0.030 to 0.050 for 24 A.W.G.<br>0.026 to 0.040 for 26 A.W.G. |
| Weight of dry pulp—grams per foot. | 0.045 to 0.12 for 24 A.W.G.<br>0.040 to 0.095 for 26 A.W.G. |
| Density—ratio of fiber to total volume | 35% to 55%—independent of gage |

The surface of the insulation has a rather rough blotting paper appearance, though some variation is possible by changes in the beating. The cross-section is circular with the conductor in the center in the ideal case, but because of limitations imposed by practical operating considerations there is a tendency toward some eccentricity and flattening of the insulation.

## DESIGN OF PULP INSULATED CABLES

Telephone cable circuits are normally subjected to only a low dielectric stress; this permits their being placed in close proximity to one another. Thus the primary requirement of the insulation is that it be distributed in a thin layer of uniform application, with the wire well centered so that each conductor when packed into a cable is completely insulated from its neighbors throughout its length. The mean radial thickness of the pulp insulation for the 26 A.W.G. wire is less than 0.01 in., and for 24 A.W.G. wire is about 0.011 in. The pulp is prepared and applied to the conductor in such a manner that the fibers pack together to form a cover with sufficient strength and elasticity to withstand the handling the insulated wire must receive and yet be as light as possible in weight per unit volume in order to obtain the best electrical characteristics.

Pulp insulated wire is structurally more like textile insulated wire than air spaced paper ribbon insulated wire. The insulation is firm with no appreciable air gap between it and the wire, and bundles of wires nestle together differently when grouped into a given space. Furthermore, it was found that when pairs of conductors were stranded together in the usual manner of concentric layers each reversed in direction, the unit thus formed was considerably less flexible than the standard construction. This is apparently caused by the greater frictional resistance between layers, thus causing sharp kinks for even moderate bends. While this feature is less pronounced for small cables, it is, of course, objectionable and an improvement in the handling qualities is effected by stranding several layers in the same direction rather than employing the single reverse layer construction.

For the large size cable, a design whereby the pairs are first grouped into units of 51 or 101, all the pairs in these units being stranded in the same direction and the units then stranded together into a cable, gives a construction which seems to offer the most satisfactory arrangement. Thus, for example, a 1,212-pair cable is made up of 12 units of 101 pairs each, arranged with 4 units in the center and 8 in a surrounding layer, and an 1,818-pair cable is laid up with 2 units in the center surrounded by 6 units in the first layer and 10 units in the second layer. A short section of 1,818-pair 26 A.W.G. cable with the units separated is shown in Fig. 3. One might expect these rather large units would not group themselves together into a circular shape without poor utilization of the space they occupy but it has been found that by properly constructing the individual units and by suitable arrangement of the cable layup, a cross-section is obtained with the groups keystoning together nicely and presenting no noticeable voids.

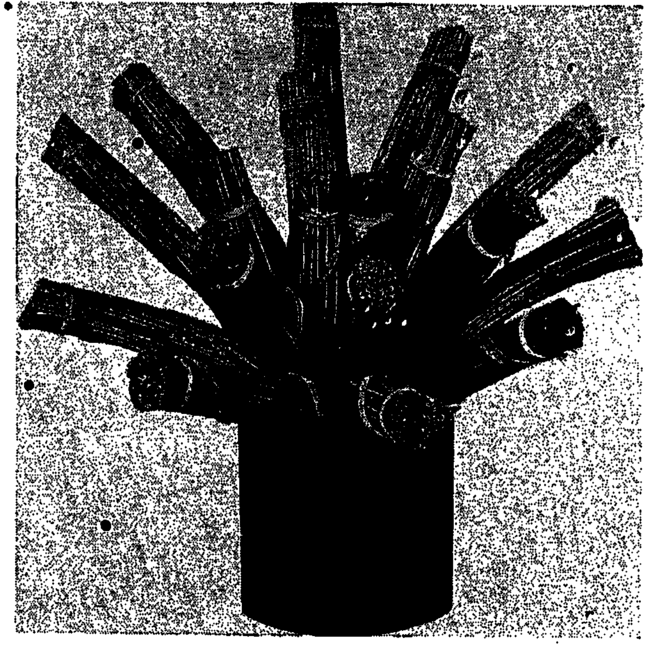

**Fig. 3. Section of 1,818-pair 26 A.W.G. cable showing units separated**

The cable core must also have a certain firmness or density to give the best support to the sheath and insure satisfactory handling as the cables are being installed. With ribbon paper insulation the ratio of the amount of insulation to the non-copper space in a cable was found to be a fairly good criterion of the firmness required. With the fundamentally different physical characteristics of the pulp insulated wire this relationship was altered and experimental trials were therefore necessary to determine the approximate size of pulp insulated wire most suitable for the space it was to occupy in cable form. There is some latitude here in the distribution of a given amount of fiber but taking into account both the mechanical and electrical requirements, the diameter for the insulated conductor finally selected as the most satisfactory for the series of standard cables of 24 A.W.G. was 0.041 in. and for 26 A.W.G., 0.033 in.; and the aim in manufacture is to produce an insulation as uniformly close to these dimensions as possible. These diameters are measured by a volume displacement method. Short samples, as representative as possible of the wire under consideration, are inserted for a given distance into a small bore tube of mercury and the displacement noted. The gage is calibrated so that mean diameters are read directly on the scale.

The above specific sizes of pulp insulated conductors apply only to cables designed for a particular set of characteristics. As in the case of ribbon paper cables, the amount of insulation for a given gage of conductor may be varied within reasonable limits, so as to produce cables of other characteristics.

## ELECTRICAL CHARACTERISTICS

It was reasoned that pulp insulated cables would probably be inherently higher in mutual capacitance than similar sizes of paper ribbon cables because, considering the insulated wire itself, in the case of helically applied strip insulation the volume of air beneath the paper is about equal to the volume of the paper itself, while for pulp insulation there is very little air space between the insulation and the wire. This fundamental difference could be somewhat compensated for, however, by the introduction of more air into the spaces between the fibers of the pulp insulating medium than is found in the paper ribbon itself, but it was not expected that it would entirely neutralize the effect of lack of air space next to the wire. It was appreciated, however, that the aim should be to get as low density insulation as possible still consistent with obtaining a continuous, flexible, and strong covering on the wire and emphasis was placed on this phase from the start of the development. In Fig. 4 is shown graphically the progress that has been made in reducing the mutual capacitance of 24 A.W.G. cable since early in 1928. Although a substantial improvement has been made in lowering the mutual capacitance to within less than 4 per cent of the corresponding ribbon paper cable, a further reduction would have considerable value, warranting more effort in that direction. For 26 A.W.G. cable the excess in capacitance is even less than for 24 A.W.G., and furthermore, it is not so objectionable from a transmission standpoint as in the case of the larger gage.

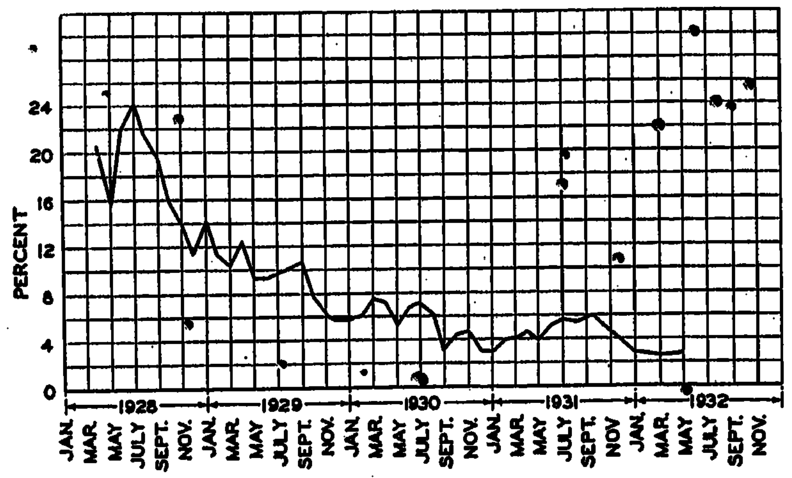

**Fig. 4. Curve showing improvement in mutual capacitance since early 1928**

The percentage is that by which the capacitance of 24 A.W.G. pulp insulated cables exceeds that of ribbon insulated cable

The principal factors which have brought about this reduction in capacitance are improvements in the treatment of the pulp itself, refinements in machinery operation to permit the use of a lower density covering on the wire, the more rapid drying out of the moisture from the pulp resulting in less shrinkage of the insulation on the conductors, and the producing of more nearly round and better centered insulation. Of these factors perhaps the one having the greatest effect on lowering the mutual capacitance was that of improving the out-of-roundness of the insulated conductors. In studying this phase of the problem, advantage was taken of the effect of flatness of the insulation on the component parts which make up the mutual capacitance. The mutual capacitance of a pair of wires is composed of the direct capacitance between the 2 wires augmented by a series arrangement of 2 other direct capacitances, one from each of the 2 wires to the grounded group consisting of all other wires and sheath. As 2 wires with oval shape insulation are twisted, there is a decided tendency for 2 flat sides to stay together resulting in the average separation of wire and mate being less than where circular sections are involved. To determine accurately the degree of out-of-roundness representing the average condition throughout a length of cable by mechanical means is next to impossible, whereas the direct capacitance between wire and mate automatically integrates this condition. Measurements therefore are made of the component direct capacitances and their ratio used as a sensitive indicator of the effect of flatness of the insulation on the mutual capacitance. By using the ratio of capacitances the cable length error is eliminated and accurate determination can readily be made on short lengths of cable. In Fig. 5 and Table III are given data which were obtained on 4 short lengths of pulp insulated

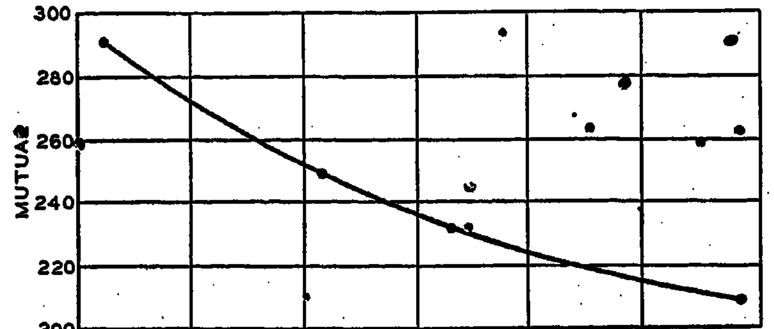

**Fig. 5. Curve showing mutual capacitance versus direct capacitance to ground divided by direct capacitance to mate**

cables which so far as was known differed only as regards the lack of symmetry of the insulation.

The a-c mutual conductance follows the trend of the capacitance, resulting in the ratio of conductance to capacitance at a frequency of 900 cycles per sec being somewhat higher than the standard ribbon paper cable, but not of a magnitude such as to introduce any serious transmission loss for these fine gage circuits. The d-c insulation resistance is of the same order as that of strip paper cables.

The dielectric strength of the insulation is ample, being somewhat higher on the average than that of similar strip paper cables. A rather extensive series of mechanical tests comparing pulp and ribbon types of insulated cable under controlled conditions simulating those met with in actual installation, showed that the pulp insulated cables remained superior to the ribbon cables as regards dielectric strength but that under extreme loads they would not withstand quite as much stretch as the ribbon insulated cable without mechanical damage to the insulation.

## Installation Features

No new features are involved in installing pulp insulated cable except in the splicing of the conductors after the lengths as supplied from the factory have been placed in position in the plant. This operation, however, is a considerable factor in the total time of the installation procedure because in a not unusual run of a mile of an 1,818-pair cable, there may be as many as 40,000 joints to be made involving the stripping of twice that number of ends of insulated wire preparatory to joining the copper conductors.

Immediately upon removing the lead sheath from the ends of the cables thus exposing the dry insulation to the atmosphere, absorption of moisture rapidly takes place. It is customary therefore to boil out the ends of cable with paraffin wax before starting the splicing operation. With strip insulation this wax also aids in preventing the insulation from unfurling. It was found that even the most flexible pulp insulation so far produced, when impregnated with unmodified paraffin, would not withstand satisfactorily the handling incident to splicing at low temperatures. A softer and more lubricating type of compound is required and a suitable combination has been found by adding paraffin oil to the paraffin wax. Different proportions of oil and wax are used depending upon the temperature at the time of installation, and the compounding is done at the point of splicing. At an atmospheric temperature of about 75 deg F no oil is required and below 10 deg F about half oil and half wax makes a suitable compound with proportionate amounts of oil for intermediate temperatures. In Fig. 6 is shown the stripping characteristics of typical pulp insulation on a few inches of 24 A.W.G. conductor impregnated with compounds of different proportions of paraffin wax and oil.

Table III—Capacity Measurements Indicating Symmetry

Mutual Capacitance vs. $\frac{\text{Direct Capacitance to Ground}}{\text{Direct Capacitance to Mate}}$

Average Value in $\mu\mu f$.

| Sample | Mutual | $D_M$ | $D_G$ | $D_G/D_M$ |
|---|---|---|---|---|
| 1 | 292 | 187 | 201 | 1.07 |
| 2 | 250 | 144 | 207 | 1.42 |
| 3 | 233 | 126 | 209 | 1.66 |
| 4 | 206 | 101 | 221 | 2.19 |

In starting to make a splice, the insulated conductors are brought together in proper position, given a sharp crossover, the wires cut off so as to give several inches of free end, the insulation broken at the crossover, and then stripped off the ends. Thus the ideal insulation is one which when waxed can readily be parted at the crossover and when broken will slip freely along the wire, yet will withstand considerable bending and folding at other places in the splice without breaking. Pulp insulation tends to cling to the conductor somewhat more than a paper tube of strip insulation and although there is considerable variation in this characteristic in the product as now manufactured, it is sufficiently under control so that with a small amount of experience a splicer applying his usual technique is able to handle even 26 A.W.G. wire with little breaking of the conductors. There is, of course, with pulp no raveling of the insulation and the cotton sleeves which are used to insulate the joint, slip over the ends of the wires rather more readily than for the spirally applied paper. Thus the over-all time required for joining a given number of pairs is practically the same for the 2 types of insulation.

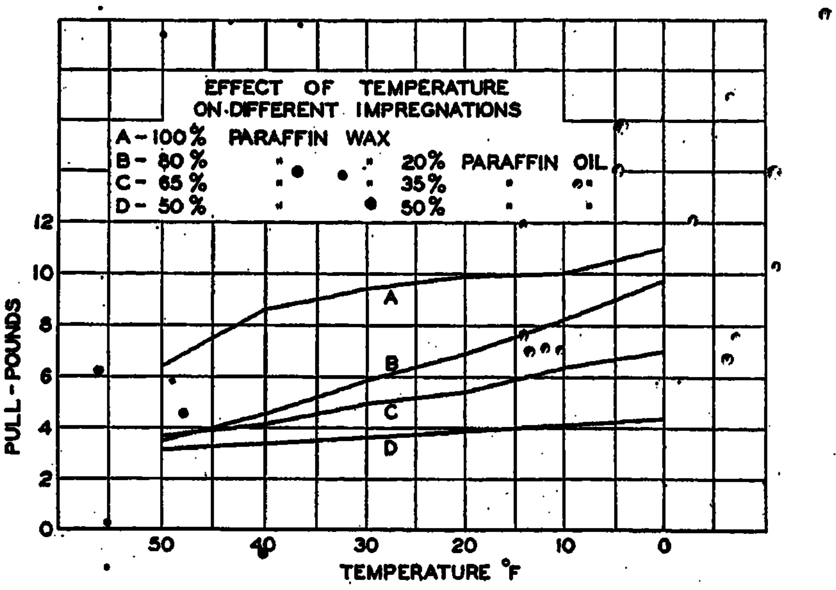

Fig. 6. Curve showing effect of atmospheric temperature on pull required to strip insulation impregnated with various wax and oil mixtures

An unbleached pulp is used and the natural brownish color of the Kraft stock results in less sharp color distinction for the different groupings of pairs than where ribbon insulation is used. However, by simplifying the color code so as to require only red, blue, and green, besides the natural color, sufficient contrast in the shades is obtained so that there is no difficulty in distinguishing colors in the splicing operation.

Preliminary cost figures indicated that this process offered the possibility of a considerable saving over the ribbon process. These predictions have been verified by actual machine operation extending over a period of more than 3 years. The savings are made possible by the low cost of Kraft pulp as compared with manila paper and by the elimination of the intermediate paper making, paper slitting, and handling operations.

---

# Dynamic Braking of Synchronous Machines

**Accurate and practical formulas for determining the number of revolutions and time required to stop a synchronous machine by dynamic braking are presented in this article, thus enabling the prediction of dynamic braking performance comparable with that of other machine characteristics. The method is new to the extent that it treats variable speed short circuits.**

By

ASSOCIATE A.I.E.E.

**I. A. TERRY**
ASSOCIATE A.I.E.E.

Both of
General Elec. Co.,
Schenectady, N. Y.

ROTATION of synchronous machines frequently must be stopped as quickly as possible. The electrical methods of accomplishing this are plugging and dynamic braking. Plugging consists of reversing the phase rotation of the voltage applied to the armature winding. Dynamic braking consists of short-circuiting the armature through an external resistor and maintaining field excitation. Following a comparison of these 2 methods, the results of an analytical treatment of dynamic braking are given.

Independent of the type of braking used, the stored energy in the rotating system must be converted into some other form, usually heat. Analyses of a number of particular applications of synchronous motors to steel and rubber mills, where quick stops are necessary, have shown that practically all of the stored energy in such systems is in the motor rotor. The normal means of dissipation of this energy are the windage, friction, copper and core losses of the motor, and the friction of the rolls. Generally, unless the rolls are loaded, the amount of energy dissipated in them is negligible, being of the same order of magnitude as their stored kinetic energy. The neglect of both these factors is therefore a compensating error. The other means of energy dissipation are functions of the method used.

In plugging, the phase rotation of the supply voltage is reversed, the performance then being similar to that during starting except that the motor slip varies from two to one instead of from one to zero. At the time the speed becomes zero, the power must be removed to prevent a reversal of rotation. This method of phase reversal is subject to several outstanding objections, the most prominent of which are:

1. Unless the power supply is large, the system disturbance resulting from the switching operations may be very undesirable.
2. The torque developed for a usual motor is small, thus limiting the rate at which the system can be stopped unless a specially designed amortisseur winding is used. This special design of amortisseur winding, beneficial to stopping, frequently is detrimental to other machine characteristics.
3. If reversal is to be prevented, the power supply must be controlled accurately so that it may be removed at the instant the motor reaches zero speed. This introduces complications in the control circuits which can be avoided by other stopping methods.

In dynamic braking the armature is short-circuited through an external resistor and field excitation is maintained. The operation is that of a generator short-circuited through an external resistor. The theory of such operation from the standpoint of constant speed has been treated thoroughly in previous publications. The dynamic braking cycle differs from these treatments in that as the rotational energy of the system is dissipated, the speed of the machine decreases. The rate of this dissipation depends greatly upon the resistance used, as will be shown.

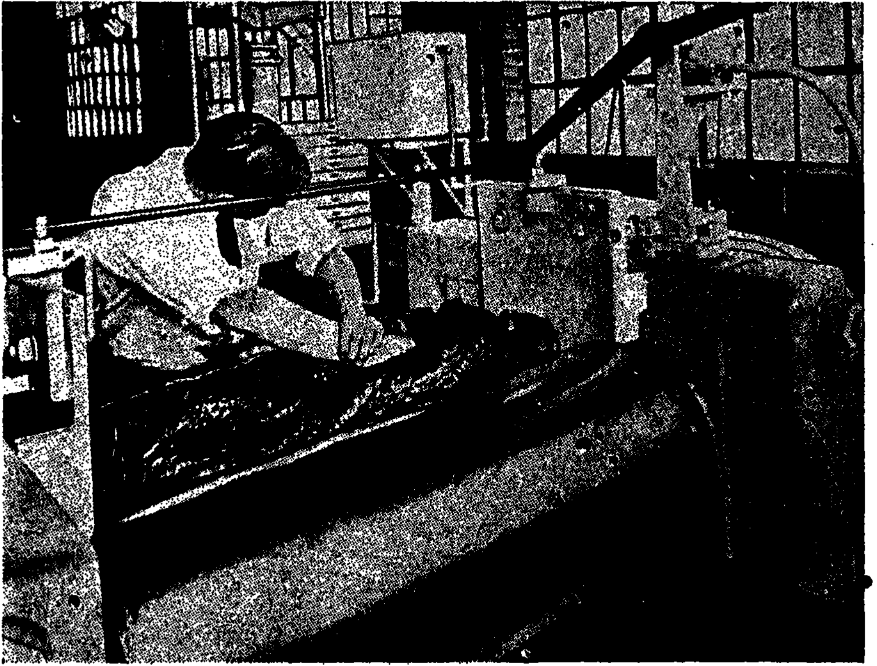

**Fig. 1. A typical application where rapid braking is necessary**

In order to present a comparison of the 2 methods, Table I has been prepared showing the number of revolutions made before stopping and the time in

---

Full text of "Dynamic Braking of Synchronous Machines" (No. 32-67) presented at the A.I.E.E. summer convention, Cleveland, Ohio, June 20–24, 1932.

seconds required for each of the 2 methods. The figures are based on an average 1,000-hp unity-power-factor, mill-type motor. They represent calculated results based on the theory which follows.

ANALYTICAL RELATIONS

To determine the relations during the braking cycle an expression for the instantaneous armature current is obtained from the vector diagram of a suddenly short-circuited generator with known speed decrease. The instantaneous torque in synchronous kilowatts is obtained from the armature current and effective circuit resistance. This is equated to the rate of change of kinetic energy due to speed reduction. There results a differential equation which when solved gives the speed-time curve in terms of the machine constants. Experience has shown that there are 2 satisfactory methods of solving this equation. The first, based upon the assumption of constant effective excitation, gives an equation for the speed-time curve as follows:

$$t = \frac{2H}{e_d'^2 r}\left\{\frac{x_d'^2}{2}(1 - n^2) - r^2 \log n + \frac{r^2}{2}\left(\frac{x_d'}{x_q} - 1\right)^2 \log \frac{n^2 x_q^2 + r^2}{x_q^2 + r^2}\right\} \quad (1)$$

where

$t$ = time in seconds
$H$ = stored kinetic energy in kw-sec per unit normal kva
$e_d'$ = excitation behind transient reactance at the instant of applying the short circuit
$r$ = total internal and external armature resistance
$x_d'$ = direct axis transient reactance
$n$ = per unit speed
$x_q$ = quadrature axis synchronous reactance.

The number of revolutions made by the machine upon reaching a given speed is then obtained by changing the variable in the speed-time equation and integrating. This is:

$$R = \frac{N_0 H}{30 e_d'^2 r}\left\{r^2(1 - n) + \frac{x_d'^2}{3}(1 - n^3) - r^2\left(\frac{x_d'}{x_q} - 1\right)^2\left[(1 - n) - \frac{r}{x_q}\left(\tan^{-1}\frac{x_q}{r} - \tan^{-1}\frac{n x_q}{r}\right)\right]\right\} \quad (2)$$

where

$R$ = total revolutions up to any time
$N_0$ = revolutions per minute at synchronous speed.

The total revolutions made to stop are found by placing correct boundary conditions in the above equation, and solving. The result is:

$$R_s = \frac{N_0 H}{30 e_d'^2 r}\left\{r^2 + \frac{x_d'^2}{3} - r^2\left(\frac{x_d'}{x_q} - 1\right)^2 \times \left(1 - \frac{r}{x_q}\tan^{-1}\frac{x_q}{r}\right)\right\} \quad (3)$$

where

$R_s$ = total revolutions to stop.

The optimum value of resistance to be used in order that the revolutions to stop are a minimum, considering all of the machine quantities to remain constant, is obtained by differentiating $R_s$ with respect to $r$ and neglecting the less significant terms. This value is:

$$r_0 = \frac{x_d'}{\sqrt{3}}$$

The second method of solution is based upon variable excitation with an assumption regarding the manner of variation. Analysis of a number of oscillograms taken during the dynamic braking cycle has shown that the field current can be represented very closely by a single exponential form, the time constant however being shorter than that of the field under short-circuited armature conditions.

Table I—Revolutions and Time to Stop

| Motor Speed r.p.m. | Plugging |  | Dynamic braking |  |
|---|---|---|---|---|
|  | Rev. | Time (Sec) | Rev. | Time (Sec) |
| 1,200 | 15.60 | 1.72 | 9.00 | 0.98 |
| 600 | 5.50 | 1.21 | 4.32 | 0.95 |
| 300 | 2.90 | 1.28 | 2.40 | 1.05 |
| 150 | 1.65 | 1.45 | 1.41 | 1.24 |
| 72 | 1.02 | 1.87 | 0.85 | 1.56 |

Using this assumption there results a relation between the machine quantities, speed and time, as follows:

$$\frac{E_f^2}{r_f^2}t - \frac{2E_f\left(I_B - \frac{E_f}{r_f}\right)}{r_f\,\alpha}(\epsilon^{-\alpha t} - 1) - \frac{\left(I_B - \frac{E_f}{r_f}\right)^2}{2\alpha}(\epsilon^{-2\alpha t} - 1) = \frac{2HI_{af}^2}{r}\left\{\frac{x_d^2}{2}(1 - n)^2 - r^2 \log n + \frac{r^2}{2}\left(\frac{x_d}{x_q} - 1\right)^2 \log\frac{n^2 x_q^2 + r^2}{x_q^2 + r^2}\right\} \quad (4)$$

where

$E_f$ = volts, field
$r$ = field ohmic resistance

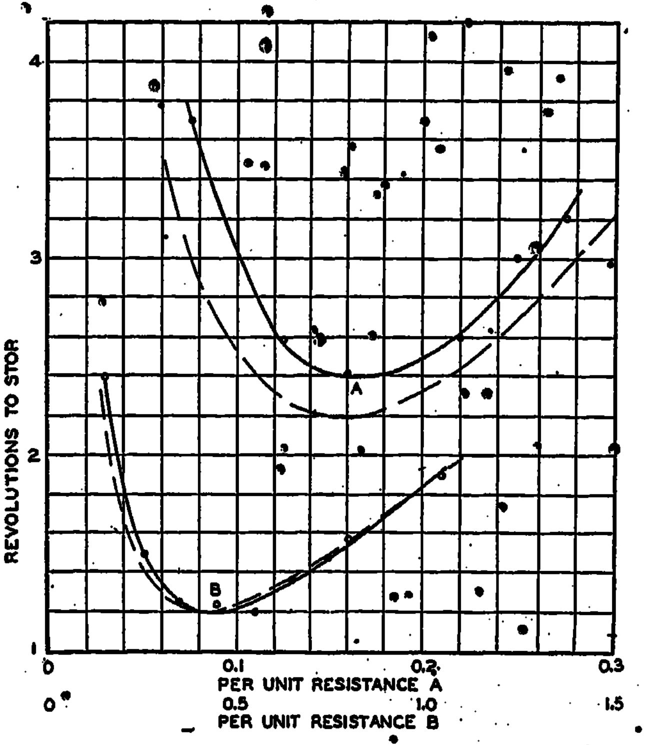

**Fig. 4. (Right) Effect of external resistance on stopping revolutions**

Curves *A*—600-hp, 12-pole, 600-rpm, 0.8-power factor motor

Curves *B*—500-hp, 40-pole, 180-rpm, 0.8-power factor motor

Test curves in full lines

Calculated curves in broken lines. (See eq 3)

$I_B$ = field amperes after disconnecting from line
$\alpha$ = apparent decrement factor of field decay
$I_{fo}$ = amperes field to produce normal open circuit terminal voltage on air-gap line
$x_d$ = direct axis synchronous reactance.

The left hand side of the equation has only time functions, and the right hand side has only speed functions. Being of transcendental character, no explicit solution is available, but the desired result may be obtained by plotting the 2 sides of the equation and finding the time and corresponding speed for which they are equal.

## Discussion of Results

The theoretical results are based on the premise that saturation may be neglected, but their application to a practical machine must include saturation effects in the determination of the initial conditions and in the determination of the instantaneous excitation. This is evident, because regardless of the initial terminal voltage applied, and the initial field current, there is some point during the speed decrease at which normal flux is reached. As the machine passes this point, saturation plays an increasingly greater part in the effective excitation. Since this excitation enters the determination of the stopping revolutions as the square, its accurate calculation is imperative. Satisfactory results would not be possible in many practical applications if saturation were omitted.

The assumption of constant effective excitation will embrace a large majority of applications, in fact will be sufficiently accurate for most calculations.

In the case of a braking cycle being initiated with the machine under load, it is interesting to note that the revolutions to stop, due to the rate of electrical energy dissipation will usually be greater than would occur under initial no-load conditions. The presence of the shaft load, if it continues, will of course aid in the stopping and bring the machine to rest sooner than the no-load condition in spite of the fact that the rate of electrical energy dissipation is less.

The effect of corrective power factor is to increase the effective excitation and consequently improve the stopping cycle. If, however, the power factor necessitates a larger diameter machine than could otherwise be used, the increased mechanical energy storage may more than offset the gain obtained from a greater rate of dissipation. The proper proportioning of a particular machine depends upon these 2 factors, and to obtain good results a careful balance must be found.

## Comparison Between Test and Calculated Results

In Fig. 2 is shown an oscillogram of the relations during the dynamic braking of a 500-hp, 40-pole, 180-rpm, 0.8-power factor synchronous motor whose constants are:

$x_d$ = 1.45 $x_q$ = 1.02 $x_d'$ = 0.65 $e_d'$ = 1.34 $N_0$ = 180
$H$ = stored energy per kva = 0.493 second
$r$ = total per-unit armature resistance = 0.53

In Fig. 3 is shown a comparison between test and calculated current-speed and speed-time curves from the oscillogram of Fig. 2. The agreement between the curves is quite satisfactory. Fig. 4 shows test and calculated revolutions to stop vs. per-unit armature resistance on 2 synchronous motors, one of which is the one given previously and the other is a 600-hp, 12-pole, 600-rpm, 0.8-power factor machine whose constants are:

$x_d$ = 0.89 $x_q$ = 0.52 $x_d'$ = 0.22 $e_d'$ = 1.27
$H$ = 0.762 $N_0$ = 600

The general shapes of the test and calculated curves are similar although there is a fairly constant difference between the curves on the 12-pole motor.

Of particular interest is the fact that the agreement between test and calculated values at the optimum resistance is quite good. This is true of the revolutions to stop as well as the current-speed and speed-time curves. As the resistance is increased or decreased with respect to the optimum the agreement is less satisfactory. The minimum revolutions as determined by the equation for $r_o$ are 2.45 for the 12-pole motor and 1.22 for the 40-pole motor. The test curves give, respectively, 2.42 and 1.20.

# Economic Aspects of Water Power

Among developments of the past decade that have enhanced the usefulness of hydroelectric power are the present large size of electric utility systems, the peaked nature of their loads, advances in long distance power transmission, and various improvements in the design and construction of hydroelectric plants. In this article the value of water power is analyzed in terms of the 2 main components of the cost of steam power—capacity and energy.

By
**F. A. ALLNER**
MEMBER A.I.E.E.

Pennsylvania Water and Power Co., Baltimore, Md.

DURING THE PAST DECADE, water power in all those regions of the North American Continent where it is employed in conjunction with thermal sources of power has undergone a gradual but pronounced change in its economic relationship to steam power. Two main components make up the economic value of water power—capacity and energy. The capacity value of hydroelectric plants, that is the cost of procuring equivalent capacity service by other sources of power, so far has not been affected measurably by advances in the art of constructing thermal plants; but the energy value or the cost of producing energy by other means has been reduced greatly in recent years.

This downward trend in energy value may be traced chiefly to 2 causes: improvements in thermal economy and the declining price of fuel; and in a minor way only to miscellaneous causes such as reduction in maintenance cost and operating labor due to improvements in design, and concentration of large capacity in comparatively few units. There is some well warranted expectation that the future trend of average fuel prices will be decidedly upward, but probably not sufficient to overbalance materially the effect of further improvements in thermal economy that may be realized in the future.

Since the total energy output for a given water power site is limited by natural conditions of discharge and head, the gain in energy output due to various refinements in the efficiency of energy conversion is necessarily only of minor importance. It is evident, therefore, that the most fruitful field of endeavor for enhancing the economic value of water power will lie in the direction of (1) reducing the investment cost per kilowatt to a point where the carrying charges will compare favorably with equivalent cost of steam power; and (2) increasing the total amount of economically installed capacity beyond the formerly accepted limits and coordinating the operation of the combined sources so that such additional economic hydroelectric capacity can be utilized to render firm peak service to the power supply system of which it is a part.

The purpose of this article is to review briefly the parallel developments in the economics of water power in respect to these 2 main components, energy and capacity, and to give an outline of future possibilities for enhancing the economic value of water power.

## Factors Controlling Choice of Hydro or Steam

Few electric systems in this country are supplied wholly by hydroelectric generation, chiefly because it has been economically advisable and often necessary to provide, by means of steam plants located near load centers, reserve generating capacity for use during periods of low water flow. There is no generally accepted ratio of hydroelectric to steam capacity for best economic results; the optimum proportion for any system is determined by the relative investment cost, fuel costs of steam energy, and characteristics of system load and water supply.

Fundamentally, the benefit derived from the 2 sources of supply comes from combining the low operating energy cost of water power with the low unit investment cost of steam; while the total investment to carry the system peak may be larger in a combined system than with steam alone, the excess investment is more than compensated by the

---

Full text of the first part of a paper "Economic Aspects of Water Power" (No. 32-128) presented at the A.I.E.E. Middle Eastern District meeting, Baltimore, Md., Oct. 10–13, 1932.

low cost of energy derived from water power. The 2 sources of power should be regarded as supplementing rather than competing with each other. Quick-starting characteristics of hydroelectric units, namely, the ability to start them from standstill and synchronize them with the load in a small fraction of the time required for steam units, provides a high degree of standby readiness for emergencies. Hydroelectric units, especially of the low head type having short water passages, are well adapted to maintain system frequency. Water storage can be drawn upon to relieve the steam plants of the task of ironing out discrepancies in the forecasting of system load demands, to save banking extra boilers and generation by less efficient units, and to facilitate the advance scheduling of equipment for generation as well as for withdrawal from service for inspection and maintenance. Hydroelectric generators also are adapted to no-load operation as synchronous condensers for voltage regulation or power factor correction without consuming much energy or requiring elaborate precautions against overheating or rubbing as in steam units.

## FIRM HYDROELECTRIC CAPACITY

The best method of operating a combined water power and steam system is generally to schedule the hydroelectric plants for maximum efficiency in periods of deficient water, and for maximum energy output in periods of plentiful water. Operation is simplified where water storage is available during low flow periods, hydroelectric capacity then can be held ready for instant use in case of emergency at associated steam plants. Water power always supplies a belt on the system load curve according to water availability such that the largest possible hydroelectric capacity is utilized; associated steam plants thus are operated at improved load factors in periods of deficient water.

That portion of the hydroelectric capacity which under certain assumed conditions (generally coincidence of highest system load demands with minimum flow) controlling the capacity investment for the system as a whole, will render the same capacity service in the upper portion of the system load curve that an alternative steam plant might perform, is called *firm hydroelectric capacity*. With large storage and favorable load conditions, the firm capacity of the first hydroelectric plant connected to a load system may be many times the minimum 24-hr power available. However, the minimum flow energy for a second hydroelectric plant feeding into the same load system will yield a relatively smaller firm capacity than the energy from the first plant, that is, the increment gain in firm hydroelectric capacity per unit of hydroelectric energy will decrease with an increase in the total amount of hydroelectric energy available.

## RECENT DEVELOPMENTS FAVORING WATER POWER

Certain factors of increasing advantage to hydroelectric development have made possible, and hold promise for still greater usefulness of, numerous hydroelectric projects that would not have been considered economically feasible during preceding years, notwithstanding the higher unit value of energy in those years. Among these factors is the present large size of electric utility systems in consequence of natural growth as well as of the interconnection of contiguous load areas. Almost without exception, new large scale hydroelectric developments are made by electric systems that supply either metropolitan load centers or a group of systems covering a regional territory.

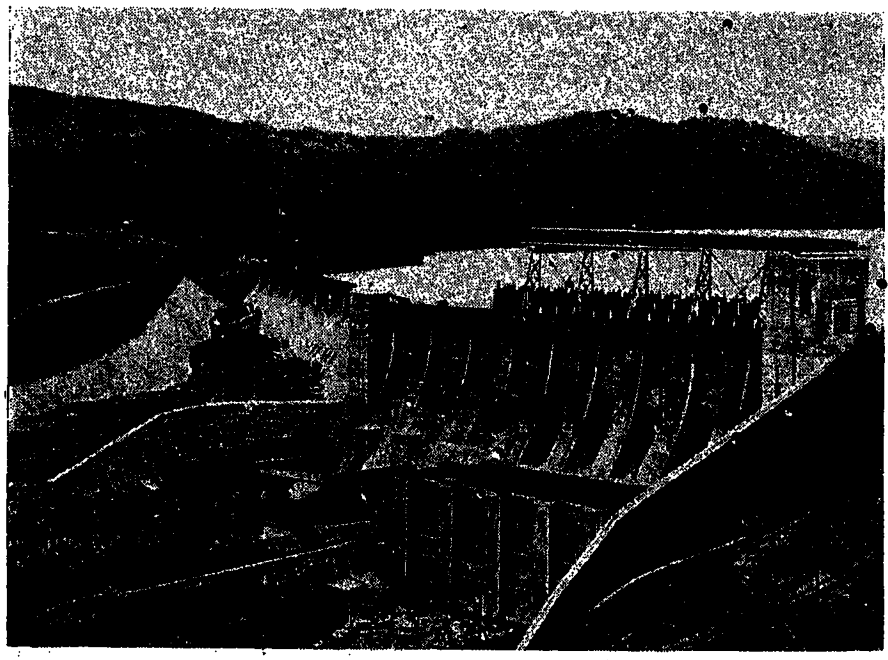

Fig. 2. Fifteen Mile Falls plant on the Connecticut River, a typical low-head storage plant

Shape of the peak of electric system loads is favorable for utilizing a large installed capacity in hydroelectric plant under minimum water conditions, which allows a large capacity value to be allotted to water power. Especially in the region along the Atlantic seaboard the sharp peaks of the various metropolitan load centers, although seasonal and of short duration, may occur simultaneously at the same hour and on the same day. This lack of assured diversity in load demand of interconnected systems, while unfavorable from the point of view of over-all power cost, gives storage-equipped hydroelectric plants an opportunity to utilize a greater portion of their installed capacities for firm peak service on the combined system.

Another feature of large utility system loads has been the annual increase in peak, which has been of such an amount that within a comparatively short time the entire capacity of new hydroelectric developments has become usable on the peak. At the same time the minimum system load is sufficient to absorb a large hydroelectric output when water is plentiful in run-of-river plants. Plants that can be developed beyond the continuous flow capacity at a low incremental cost can produce a great deal of low cost secondary energy.

Advances in the art of power transmission have made it possible to transmit large capacities over long distances at reasonable cost, with good voltage regulation and with low energy losses. In some instances step-up switching stations at the hydroelectric plants and step-down terminal stations of transmission lines can be developed advantageously as integral parts of interconnection projects; thus large power systems that formerly functioned as separate units are tied together into a regional power system extending over a large area. In this manner a dual function is performed by the transmission and tie-in investment, especially on systems where 230 kv has been adopted as the standard transmission voltage. The high degree of service reliability of all types of equipment at this voltage has encouraged designing engineers to simplify their system layouts and to rely more on higher mechanical and electrical factors of safety in equipment than on a multiplicity of lines and reserve apparatus; this has a tendency to reduce investment cost or increase the service value of hydroelectric projects. Most recent operating experience with high voltage transmission lines embodying some advanced features of design, has been so satisfactory, that lightning proof operation of transmission lines is within the range of possibility at a not too distant future.

At the hydroelectric plant proper, several factors have contributed toward lowering the investment cost, aside from the lower price levels of structures and machinery. With construction plants laid out for low handling cost and rapid progress, and with careful engineering work applied to temporary structures, flood control, etc., the period of construction has been shortened; substantial amounts thereby are saved that formerly were expended on interest and other carrying charges during construction. Economies in the cost of financing are made possible by the sponsoring or underwriting of major enterprises through existing large utility systems, and few projects are undertaken now for which the market has not been secured in advance at least to the extent necessary to insure the interest on bonded indebtedness with a sizable margin of earnings.

It is possible now to get more capacity out of a given structural space, not only because of the increased size of units, but also because of the higher specific speed of turbine runners and improved design of water passages. Higher speed and improved design of machinery have lowered the cost of main turbine and generator equipment. Auxiliary apparatus has been simplified and its cost decreased. No appreciable improvement in best efficiency of runners has been recorded during the past decade, at the beginning of which peak efficiencies in excess of 90 per cent already had been reached; however, with the advent of the adjustable blade Kaplan turbine high efficiency can be secured in low head plants over a much wider range of loading, and the over-all efficiency of energy conversion for the plant as a whole can be raised noticeably over that of earlier installations. Testing of models no longer is confined to runners and draft tubes, to observations of efficiency and output, and to studies of the cavitation problem; but extends to every phase of the project from headwater down to the lower end of the tailrace channel. As a result of model tests, more economic designs of spillways, pier and apron sections, flood gates, etc., have been developed. Effective steps have been taken at the newer plants to guard against service interference by trash and ice.

## PUMPED STORAGE PLANTS

Pumped storage plants involving specially constructed high or low level storage reservoirs do not play so important a part in the power supply scheme of large systems in the United States as they do in Europe. Several such projects are under discussion, but only one major installation, a plant built in 1928 on the Rocky River, a small tributary of the Housatonic River in New England, is actually in service. The plant pumps from the Housatonic River to a reservoir of 68,000 cfs-days usable capacity on the Rocky River. The average yearly runoff of the Rocky River is 17,000 cfs-days.

While pumping is done mainly by off-peak steam power, the Rocky River plant provides in addition seasonal storage service to other plants located below on the Housatonic River. Installation of the 24,000-kw generating unit in the Rocky River plant and the pumped storage reservoir actually added 40,000 kw of yearly firm capacity to the electric system served by the plant. The efficiency of direct recovery by the Rocky River plant alone is approximately 60 per cent, but on account of the lower plants the over-all conversion economy derived from all plants is raised to nearly 80 per cent.

## DUAL USE CAPACITY INSTALLATIONS

This novel type of development is related functionally to pumped storage plants, being based upon the principle of converting low cost off-peak energy into high value peak capacity and energy. It employs the same unit as a turbine-generator and a motor-pump set, without, however, requiring a specially constructed high or low level storage reservoir, conduits or hydraulic control equipment. It is especially adapted to those plants where the increment cost of generating and transmitting capacity is lower than that of equivalent steam capacity and where a substantial overlapping of heads can be arranged readily. Runoff characteristics should be such that, depending on the efficiency of the conversion cycle, the duration of the low flow stage, during which conversion of off-peak energy into peak energy takes place, is not too great compared with the duration of the excess flow period, during which the dual use equipment produces energy for the system. These conditions are somewhat interrelated: In some instances a large saving in investment cost may more than compensate for the extra cost of energy in conversion losses during low flow exceeding the gain in output during high flow, notwithstanding the fact that on such a project the low flow days may outnumber greatly the high flow days.

Operating the generator in reverse direction as a motor offers no serious difficulties. However, the design of different types of turbines and hydraulic structures for dual use at synchronous speed and the possibilities of variable speed electrical and hydraulic equipment have yet been developed not to such a degree that this simplified regenerative cycle can be adapted readily to those water power projects where natural conditions of the power site are favorable.

A great deal has been published in the technical literature, especially in Europe, on the principles and applications of pumped storage predicated in each instance on the employment of 2 separate hydraulic motors, one for generation and the other for pumping, and in nearly all cases also on the use of a specially constructed high or low level reservoir. Employing a single hydraulic motor for dual use omitting specially constructed reservoirs introduce substantial economies in capital investment, but involve a sacrifice in conversion efficiency.

Perhaps in the search for optimum efficiency, we are inclined at times to throw aside as unworthy of further study, the suggestion that a process admittedly inferior from a point of view of efficiency may yet be superior from the point of view of over-all economy. The simplified method of hydroelectric regeneration has not been treated so far in the technical literature. As a proper evaluation of the possibilities of this process is of some importance on account of its effect on the economics of future hydroelectric developments, the principles underlying this method as well as some empirical results from laboratory and field tests will be described in greater detail in a later article including an analysis of those factors that will limit its field of application.

## ANALYSIS OF HYDROELECTRIC POWER COSTS

Cost of hydroelectric power may be regarded as consisting of 4 main components, namely:

1. Base cost of the development, which is more or less independent of the amount of installed generating capacity.
2. Cost of generating capacity, including low voltage switching equipment.
3. Transmission investment, including step-up transformers and other high voltage equipment at the power house.
4. Tie-in investment, such as step-down transformer and switching stations, underground cables, and other special equipment necessary for delivering hydroelectric power to a distribution system or to a high voltage network.

Until quite recently it had been customary to group the first two components into the single item—cost of power plant. This practise usually was adequate for the purpose when investigating the economics of existing plants. However, segregation into the 2 components, base cost and increment cost, is almost indispensable during the preliminary or project stage of a new development in order to determine the most economic size of the initial and ultimate installation and the part that it should play in the power supply scheme of a territory. The fact that such a differentiation exists, that the 2 components can be segregated readily and that their relative magnitudes as well as their values per unit capacity furnish a yardstick for comparing one project with another, is one of the characteristic economic features of hydroelectric plants as distinguished from steam plants; in the latter the first component, base cost, ceases to be an important factor after more than one generating unit is installed.

Cost of dam, property, flowage rights, construction equipment and temporary structures, relocation of bridges, highways, railroads, general site improvements, a certain minimum of tailrace excavation, auxiliary station equipment, all of which to some extent are independent of the amount of capacity installed, constitute the base cost. For many reasons this cost for almost identical hydraulic conditions of head, average discharge, and length of backwater, may show variations of several hundred per cent.

The second component comprises the cost of generating equipment, hydraulic as well as electrical, power house substructure and superstructure, low voltage switching and auxiliary equipment, intakes, control equipment, increment tailrace excavation, and related equipment. It sometimes is called the

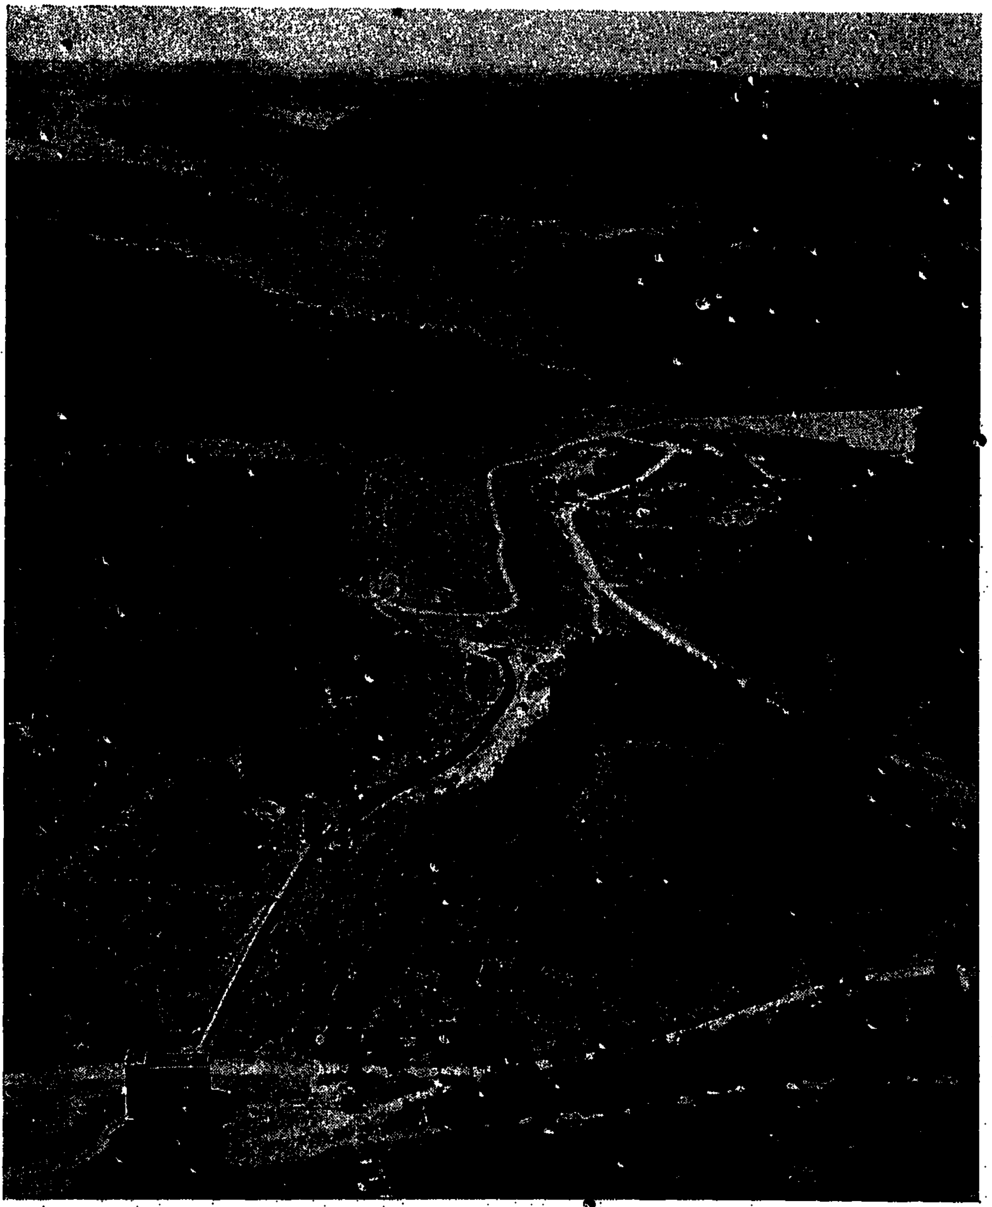

**Fig. 3. Rocky River plant of the Connecticut Light & Power Company at the junction of the Rocky and Housatonic rivers near New Milford, Conn., the only major pumped storage plant in the United States**

The plant is situated on the Housatonic River, being connected to the storage reservoir on the Rocky River by a single penstock which serves both the 30,000-kva turbine-generator unit and 2 8,100-hp pumps; provision is made for a second penstock at the Y-connection just beyond the surge tank. What appears as a black line just above the dam is a boom to protect the dam from wave action. The circular tower at the left end of the dam contains the trash racks and intake gate to the penstock. For a description of the development see A.I.E.E. Trans., v. 47, 1928, p. 1,100–07 incremental cost of hydroelectric capacity. For similar hydraulic conditions this second component, expressed in dollars per kilowatt, is almost constant except for major fluctuations in price levels and for differences in accessibility of the power site. Even over a wide range of hydraulic conditions it rarely will deviate more than 25 per cent from the average, which is approximately $60 per kw.

Considering the approximate constancy of incremental cost and the great variation of base cost, a full answer to the question whether a hydroelectric plant is a high or low cost development, cannot be given unless total power plant costs are segregated into these 2 components. For purposes of illustration, the values used in Figs. 4 and 5 have been selected as representative averages for a low-head pondage-equipped run-of-river plant, located on the eastern slope of the Appalachian range.

During the project stage, when only estimated and not actual cost figures are available, this approximate division of cost may be obtained by plotting against kilowatts of installed capacity as abscissa the estimated cost for the minimum capacity ($C_{min}$) as well as for the maximum capacity ($C_{max}$) under consideration. The point of intersection of a straight line, drawn through these 2 points, with the axis of cost will give the approximate value of the base cost component. As certain structural provisions usually must be made initially to permit expansion to a larger ultimate capacity the actual cost of the minimum capacity installation ($C_{min}$) will be somewhat higher than the estimated cost of minimum capacity exclusive of these provisions for future expansion.

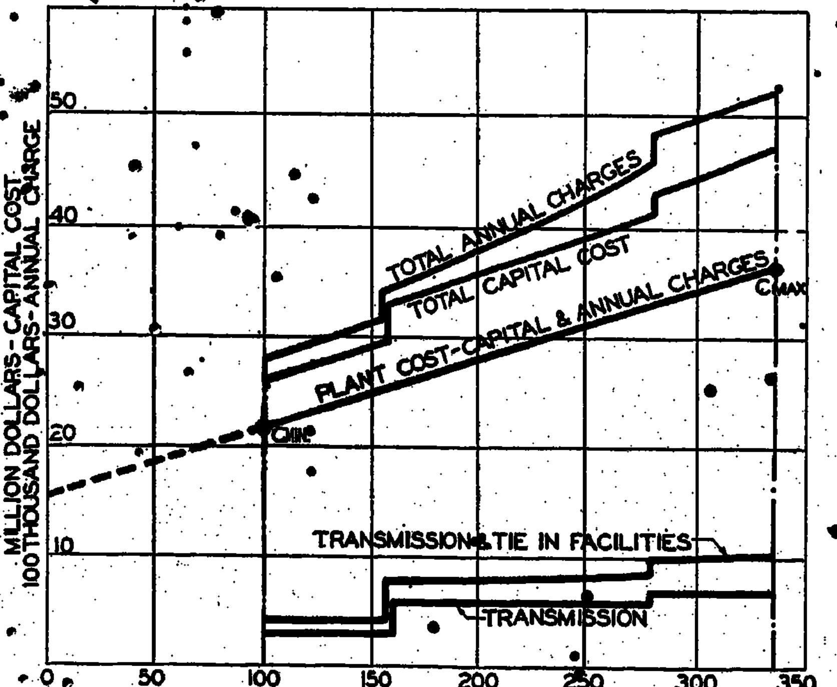

Fig. 4. Analysis of the cost of a hydroelectric project

The vertical scale in Fig. 4, representing capital cost, can be converted readily into a proportionate scale of annual charges, for the sum total of interest charges, taxes, depreciation, operation, maintenance, and other expenses, is approximately proportionate to investment. In Fig. 4 the over-all rate has been assumed at 10 per cent, based upon an average return of approximately 7 per cent on investment. Depending on the method of financing, this over-all rate may be reduced somewhat especially during the initial years.

The sum of the first 2 components represents the cost of the power plant proper, controlled largely by the hydraulic characteristics of head and discharge and by local conditions at the power house site and along the shores of the pond or reservoir. The other 2 components of cost, transmission and tie-in investments, are controlled by the geographic location of the plant in respect to its potential market, and by the opportunities of effecting a physical tie-in to existing lines or distribution networks at a minimum cost. Although bearing hardly any relation to plant costs, yet these 2 components must be fully considered as cost elements for hydroelectric power. It is not infrequent that a low cost and in every other way seemingly ideal project is uneconomic by reason of excessive transmission and tie-in cost. Conversely, certain other projects may be favored by short transmission distances to load centers, nearness of existing high voltage lines, and advantageous location of step-down stations in respect to city distribution systems.

In some special cases these 2 components of costs may become a credit rather than a charge. If, for example, a large power consuming industry is so close to the power site that it can be served economically at generating bus voltage, there will be a saving in transmission cost compared with supplying power to that industry from a more distant source; or if nearby railroad lines are electrified, there may be a distinct saving in tie-in expense not only because of the nearness of the electrified tracks, but also because where the railway operates from a 25-cycle single-phase system, lower speed single-phase generators can be used instead of the customary frequency converting equipment required in connection with 60-cycle steam power. These cases are exceptional rather than average; as a rule, the combined cost of transmission and tie-in investment will appear as a charge rather than a credit for hydroelectric power. Especially where long distances are involved, such as Boulder Dam or the St. Lawrence development, the cost of these 2 components may be equal to or exceed the increment cost per kilowatt of installed hydroelectric capacity. Development of 230-kv transmission has a tendency, where large amounts of power are involved, to reduce the transmission cost for a given distance, but to increase slightly the tie-in cost.

As extensions are made at the hydroelectric plant the cost of transmission will increase in sharp steps corresponding to the building of additional transmission lines, but the tie-in costs usually will grow at a gradual rate, corresponding to the step-by-step installation of additional underground cables and other tie-in equipment to keep pace with the increase in hydroelectric capacity. Annual charges for transmission and tie-in facilities will bear again a proportionate relation to the investment, but at a somewhat higher rate (12 to 15 per cent) than that used for the annual charges of the plant proper.

While it may appear academic to combine at an

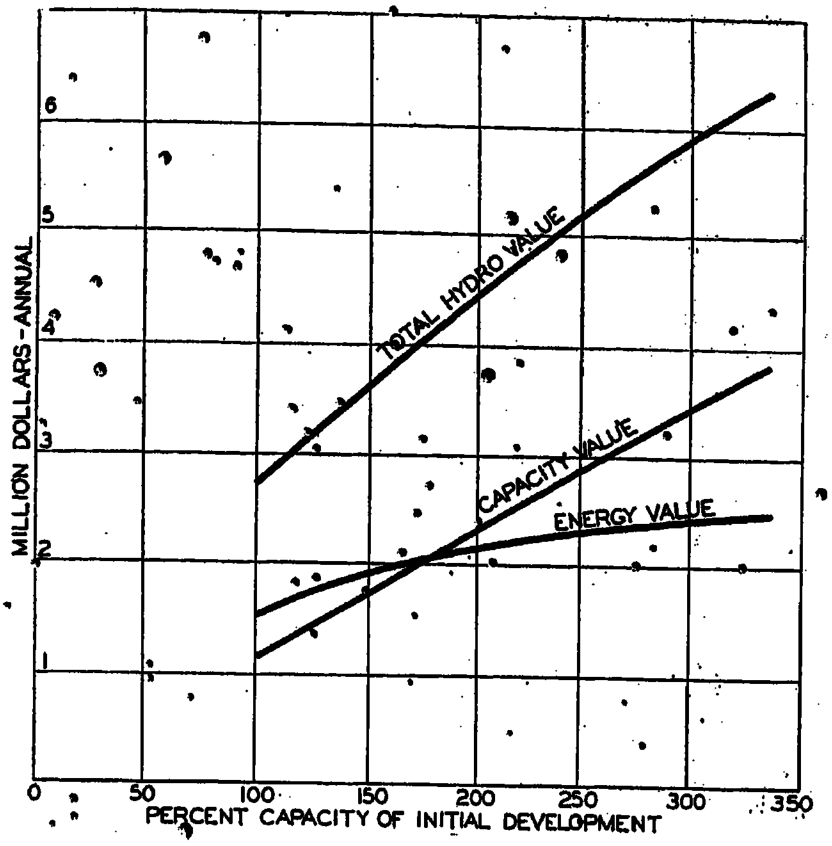

**Fig. 5. Analysis of the value of a hydroelectric project**

early stage of the project the estimated cost of the plant proper with the cost of transmission and tie-in facilities which are indirectly dependent upon marketing the power, yet a tentative forecast of these cost components is indispensable to a preliminary investigation of the economic justification of a project. Instead of adding these 2 components to the other costs of hydroelectric power, they could be subtracted from the composite value of the power, which is analyzed in the paragraphs that follow. This latter method, however, would not give as clear and convenient a graphic picture of the relationship of over-all cost and value.

## VALUE OF HYDROELECTRIC POWER

The generally accepted yardstick for evaluating hydroelectric power is the replacement cost of its 2 main components, capacity and energy, by the cheapest alternative source of supply—steam. Hydroelectric projects that have only a single potential market for their output, are more readily analyzed than those projects that have several possible outlets for power and the operation of which can be so coordinated with the operation of several steam plants that hydroelectric power renders the relatively most useful, and therefore the most valuable, service to the combined system.

Aside from the replacement value of water power as measured by the steam yardstick, a hydroelectric plant, by proper coordination of power house discharge, may add materially to the energy and capacity output of any plants located farther downstream. There are also several other collateral or contingent advantages of hydroelectric power which would be difficult to express in definite figures. Some of these features have been referred to in previous sections of this article dealing with the choice of water power or steam as a source of supply. For the purpose of this approximate analysis, however, all of these collateral features are omitted and evaluation of water power is confined to the 2 main components, capacity and energy.

It is evident that there can be credited toward the cost of hydroelectric capacity only an amount equal to the cost of equivalent steam capacity that would render a corresponding amount of firm peak service on a given system load, and that otherwise would have to be provided in the form of steam investment in order to insure adequate reserve capacity for the system. Strictly speaking, this definition would limit in the initial year the capacity value of a hydroelectric plant of any type to the annual increase in connected system load, or at the most, to the capacity of a single steam unit if the latter is larger than the anticipated increase in system load. This rather narrow definition gradually is giving way to the long range point of view, taking into account the average capacity value rendered over an extended period.

For a given amount of minimum flow energy, the amount of hydroelectric capacity that can render firm peak service to a system will increase gradually with the growth of system load, provided the load curve at least in its upper portion retains approximately the same shape. If additional load areas that previously supplied all of their requirements by steam can be tied in to a new hydroelectric plant the firm peak service rendered to the combined system will be increased materially. This is true provided, of course, that these new loads are similar in character to those originally served by the plant.

Capacity value per kilowatt comprises, in addition to the fixed charges—interest, depreciation, taxes, insurance, and some general expense—those items of steam plant operating costs that are more or less independent of the amount of power generated. This combined value varies somewhat in different localities. Aside from differences in price levels, it probably is more affected by the size of individual steam units than by any other single factor. Under

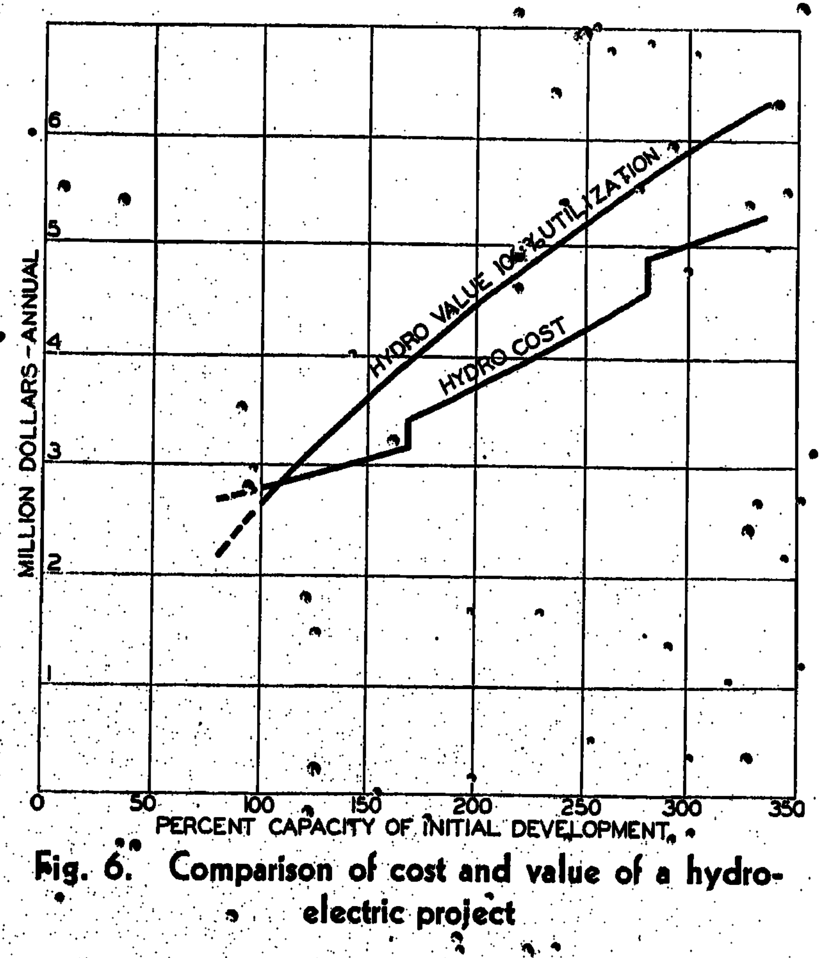

**Fig. 6. Comparison of cost and value of a hydroelectric project**

present conditions its lowest value is perhaps in the neighborhood of $10 per kw but in some instances exceeds $18 per kw for modern medium sized stations; the average is in the neighborhood of $13 which is the value used in Fig. 5.

The energy value per kwhr comprises, in addition to the cost of fuel and maintenance, only some minor items of operating supplies and labor. Depending mainly upon the price of fuel in the territory, upon the heat cycle of the station, and upon the relative size of boiler and turbine units, the energy value under present conditions may be assumed to vary (except for mine-mouth plants) from a minimum of around 2 mills per kwhr, or slightly less, to a maximum of around 3 mills, the average being perhaps 2.5 mills for unit capacities of 50,000 kw and higher. This latter value has been used for computing the total energy value of the hydroelectric project analyzed in Figs. 4 and 5, assuming full utilization of the water power available.

In order to approximate the effect of transmission losses, of capacity reductions by flood stage, drawdown of pond, etc., certain reductions have been applied to energy as well as to capacity. For less than full utilization of either installed capacity or available water power, the combined curve will drop below the values indicated, the amount of which reduction can be determined readily as a proportionate reduction of the respective component parts.

Composite curves of hydroelectric costs and values have been replotted in Fig. 6 to bring out more clearly certain trends frequently observed in connection with major hydroelectric projects serving a large interconnected load system supplied by water power and steam. During the initial years of operation, water power will compare less favorably with steam than during later years. However, a reasonable expectation is that a hydroelectric plant which has low incremental cost and not unduly high cost of transmission and tie-in facilities in the long run will yield a substantial margin of savings below the cost of steam. In addition, there will be several collateral advantages to its credit, which have been omitted in this graphic presentation.

# Metal Deposition in Electric Arc Welding

**Experimental work here reported indicates that liquid globules are the chief form of metal transfer in electric arc welding. A new method of high speed "recording" produces a metal record which can be compared directly with a corresponding oscillogram.**

By
GILBERT E. DOAN

Schenectady, N. Y.

METAL TRANSFER is one of the most important functions of the electric welding arc. Whether the metal deposited passes through the arc as vapor, as mist, or as globules larger than mist, long has been under discussion; as also has been the nature of the driving force of transfer, particularly in overhead welding where the counteracting force of gravity must be overcome.

Some students of this phenomenon have thought that the larger part of the metal is transferred as vapor generated at the tip of the wire electrode and condensed in the crater formed on the object welded. Others, pointing out the large amount of energy required to vaporize the metal at the tip of the electrode, have reached the conclusion that the principal transfer must occur as mist or globules of molten metal. Some have attributed the driving force to the evolution, within the melting tip of the electrode, of gas which results in a succession of tiny explosions discharges particles of the metal. Still others have explained the transfer as resulting from the forces of adhesion and surface tension between the molten metal on the electrode tip and that in the crater when the 2 liquids touch each other.

Another theory recently revived cites the "pinch effect" as accounting for the force necessary to separate the globules from the electrodes. (This subject is reported at length by F. Creedy and, with discussions thereon, recorded, on p. 556–66 of the A.I.E.E. Trans., June 1932.—*Ed.*) Finally, this last theory has been supplemented by discussion which suggests that the globule is propelled from the electrode by the forces resulting from the tremendous current density existing in the neck or filament of metal formed just as the globule is being separated from the electrode.

Other experimenters have found that whereas they were able to do overhead welding with ordinary steel wire, they were unable to do it with a wire of pure iron free from gas. This would seem to indicate that the combined action of "pinch effect" and surface tension, or "pinch effect" and vaporization of the

---

From, and presenting essential substance of, a paper presented at the Fall meeting of the American Welding Society, Buffalo, N. Y., Oct. 4, 1932.

pinched part of the conductor, is insufficient to transfer the metal against the force of gravitation without the help of the expulsive action of gas contained within the melting tip of the electrode.

All these experiments and theories emphasize the importance of the mechanism of metal transfer, and reveal the incomplete state of knowledge of its nature.

A partly successful attempt to record by high speed continuous photography the forms in which metal is transferred through the arc has shown that some metal is transferred as globules and some as threads. Instantaneous conditions revealed are shown in Figs. 1 and 2. This method, of course, would not show the metal which might be transferred as mist or as vapor.

## A New Method of Study Disclosed

In the welding laboratory of Lehigh University has been developed a new and direct method of investigating this subject of metal transfer, a method which records *all* of the possible forms in which metal is transferred through the arc. The principal feature of the method involves the moving of a highly polished metallic strip under the arc at a speed sufficiently high to enable each successive deposit of metal to be made on the strip distinctly separated from the others. The metal strip, or metallic mirror, thus gives a continuous and chronological record of the character of the deposit, and each form retains its identity and is easily recognized, whereas in ordinary welding the globules, mist, and vapor merge in the molten crater and lose their identity at once.

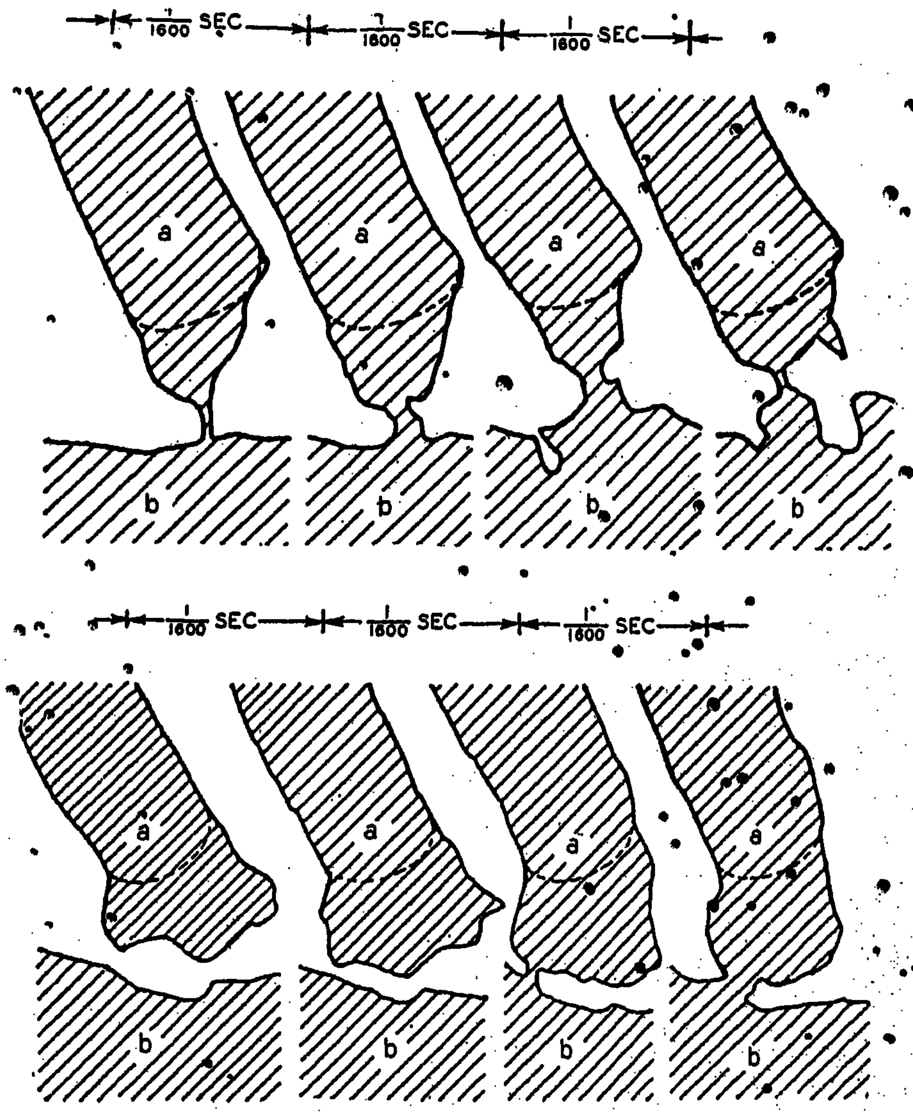

**Fig. 1. Instantaneous conditions in the transfer of metal by means of the electric arc; above, thread shaped transfer; below, mushroom shaped globules**

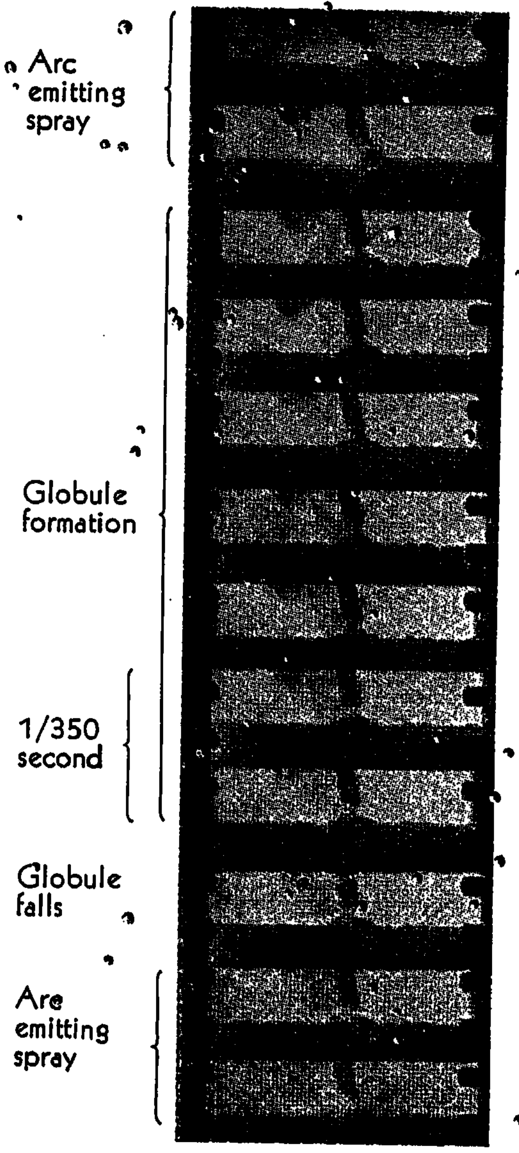

**Fig. 2. Thun's high speed photography showing a cycle in electric deposition**

In the Lehigh experiment a polished strip of mild steel 4 x 36 x $^1/_4$-in. in dimensions was run through an automatic welding machine at a rate of speed in excess of 100 in. per min, using a $^5/_{32}$-in. mild steel wire, a current of 150 amp, and somewhat more than 20 volts across the arc. The energy was supplied from a standard arc welding motor generator set. Results as shown in Fig. 3, where it may be noted that the flattened globules ranging between $^1/_{16}$ and $^3/_{16}$ in. in diameter at the base, clearly are shown to form the major portion of the deposit. Many of these show a gas cavity caused by the escape of dissolved gas as solidification took place. Under the conditions of this experiment, any vapor was oxidized before deposition and appeared on the strip as a red powder. The particles of spray also were oxidized, although probably only to $Fe_3O_4$, as a result in the decrease of surface-to-volume ratio in the larger spheres. To condense these two forms of deposition unoxidized the air about the arc would have to be replaced by an inert gas such as argon. Examination indicates that, in this case, the amount of material deposited in these forms was considerably less than 10 per cent of the total deposit; and that the chief form of transfer was as liquid globules.

Conditions involved in this test differ, of course, in some respects from those of ordinary welding. For instance, the heating of the strip under the rapidly advancing arc is insufficient to cause crater formation. Surface fusion does take place, however, beneath each globule, even at this speed, as examination shows the globules are tightly welded to the plate and resist removal by the chisel. Therefore, the temperature of the strip under the arc has been at least 1,500 deg C (the melting point of steel). A temperature considerably higher than this (probably 2,450 deg C, the boiling point of iron) exists at the crater in normal welding and therefore more heat is radiated from the crater to the wire tip, but the amount of heat so radiated to the globule on the tip of the electrode, as calculated by the Stefan Boltzman law, seems to be less than 10 per cent. This would not be sufficient to vaporize any considerable proportion of the globule before it left the wire, and thus would not change appreciably the proportion deposited as globules. The conditions of this test thus are at least enough like those of ordinary practise to render them suitable for comparative investigation of the basic phenomena of deposition.

Oscillographic records of the instantaneous values of current and voltage of the arc accompanying each series of depositions were taken on a 6-ft film, a section of which is reproduced in Fig. 3 where the deposit accompanying each current peak on the film is shown below its own peak. The accuracy with which the oscillogram records the operation of the depositing mechanism is striking. The size of the current disturbance on the film corresponds quite well with the size of the globule deposited on the strip. For instance, the overlapping globules at the extreme right correspond to the group of current peaks on the film above it, and the same correspondence holds for the double globule near the center of the series. The tiny globules of spray seemed to bridge the arc sufficiently to give a voltage "zero," although the time was too short for appreciable growth of current. This voltage zero indicates that the deposition was not entirely a spraying process even for these tiny globules. The same momentary voltage zeros appear in several other places where spray is found.

The globule next to the left of the sprayed group (in the direction of motion) illustrates the simplest case, a single globule and a single current peak and voltage valley. Likewise, the next to the left shows a double globule and double peak, but its neighbor (third from left) and also the second one from the left, both show more peaks than globules, due perhaps to complete merging of the globules before solidification.

It may be interesting to note that the largest peak of a group is nearly always the first one, possibly indicating the transfer of accumulated liquid at the tip of the electrode. Also, one notes that between the peaks of a group the voltage rises to full arc voltage, with a very short overshoot of voltage above normal, whereas the current in the valleys between peaks does not drop fast enough to reach the normal current value in the short interval. The ordinary ammeter and voltmeter used in welding show, of course, only the average current and voltage, and do not show these rapid fluctuations.

In general, the correspondence between metal deposition and oscillographic record is surprisingly accurate. Eleven other complete strings of globules with oscillograms to accompany them were made, using a variety of electrodes, currents, and speeds, each with the general results the same as described.

## CONCLUSIONS

These experiments indicate that liquid globules are the chief form of metal transfer, although there is some metal transfer as vapor and mist. A close correspondence is seen between the individual types of deposit and the individual features of the current and voltage waves on the corresponding oscillogram. The oscillogram would seem to be a trustworthy indicator of the depositing mechanism.

This method, revealing as it does the mode of metal deposition, offers also a means for testing and comparing the depositing performance or so-called "weldability" of various types of electrodes. The results of tests of this kind may be interpreted, moreover, both for hand and for automatic welding.

These results are for "bare," or very lightly coated, electrodes. The modern heavily coated electrode, because of its chemical protection to the metal in the arc, can and does use a longer arc length, in fact, so long that the globules are unable to bridge the arc and to cause the current peaks and voltage zeros of "short arc" welding. Globules are believed, however, to be the chief form of transfer, also when the longer arc and coated electrode are used. This question could readily be decided by the use of the method described in this paper, using heavily coated electrodes.

# Synchronous Motors in Rolling Mill Service

Improvements in the synchronous motor and its control, together with a growing recognition of its favorable first cost and operating characteristics, have resulted in its rapidly increasing application to constant speed main-rolls in metal-rolling mills, both steel and non-ferrous. A brief review of the present status of such applications, and some important controlling factors are given here.

By

R. N. EARLY
MEMBER A.I.E.E.

Both with the Electric Machinery Mfg. Company, Minneapolis, Minn.

AT THE BEGINNING of 1932 there were 161 synchronous motors totaling 231,950 hp driving main-rolls in steel mills and in copper, and brass, and other non-ferrous mills. This amount of horsepower is small compared to the total in use on metal-rolling mills, nevertheless it represents the largest part of the horsepower in constant speed motors installed since synchronous motors have been developed for main-roll drives. The types of main-roll drives to which synchronous motors are applied and the number of units and horsepower installed are shown in Table I.

These units range in speed from 900 to 62 rpm; about $^1/_5$ operate at 25 cycles, the remainder at 60 cycles; approximately $^1/_3$ are direct connected and $^2/_3$ are geared to their mills; voltages range from 220 to 11,000 inclusive.

## REQUIREMENTS AND SCOPE OF APPLICATION

In the field of constant speed rolling mill drives, the only apparent limitation to the use of synchronous motors is on those mills having heavy passes of short duration where it is practise to interpose fly-wheels between the load and the line. However, with the present large and growing capacity of power systems supplying most rolling mills, the need of protecting the line from short-time high-peak loads becomes of decreasing importance and the elimination of flywheels is a desired step toward greater drive simplicity. Several synchronous motors now are applied successfully to main-rolls, such as plate mills, where motors with flywheels formerly were considered essential.

On large reversing mills, synchronous motors must be excluded from consideration because frequent and rapid reversal is one of the important requirements. On certain smaller mills, however, where relatively slower reversal and constant speed rolling are satisfactory, synchronous motors offer possibilities. One continuous-reversing synchronous motor now is in use driving a copper break-down mill.

The torque requirements for various types of main-rolls are given in Table II. Except for cold-roll mills, the starting and pull-in torque requirements under normal starting conditions are comparatively light, 50 per cent of the full load torque of the motor usually being ample. Emergencies, however, may require the mill to be reversed or jockeyed under load. Hence, starting and reversing torques ranging from 85 to 100 per cent must be available, secured by applying a higher percentage of full voltage, or full voltage to the motor in starting. Cold-roll mills, because of the very high friction load, require high starting and pull-in torques. The pull-out torque requirements will be determined, of course, by the type of load imposed by the particular mill, with the highest values in general for those mills where rolling is intermittent and the passes are short.

Rolling mills, although similar in the main features of their construction and operation, nevertheless vary considerably in their individual load characteristics and motor requirements. In Table II the approximate torque requirements for specific mills have been set up. This tabulation also presents some approximate data on motor ratings and the load characteristics of mills which afford opportunity for application of synchronous motors. Additional comments on the groups of mills shown in Table II are given in the notes appended to the table. By graphical kilowatt charts Fig. 3 depicts the important types of rolling loads encountered.

## MOTOR CHARACTERISTICS

Values of starting and pull-in torques available in synchronous motors of normal design vary considerably, depending upon the horsepower, speed,

**Table I—Applications of Synchronous Motors to Main-Roll Drives**

| Mill | Units | Hp | Avg Hp |
|---|---|---|---|
| Billet and bar mills | 21 | 74,750 | 3,500 |
| Tube piercing mills | 20 | 41,300 | 2,000 |
| Copper and brass mills | 47 | 25,450 | 550 |
| Rod mills | 10 | 21,850 | 2,200 |
| Tube rolling mills | 8 | 11,600 | 1,400 |
| Skelp mills | 2 | 10,500 | 5,000 |
| Hot strip mills | 11 | 14,950 | 1,350 |
| Merchant mills | 11 | 9,900 | 900 |
| Tube reeling and sinking mills | 9 | 4,250 | 450 |
| Structural mills | 1 | 3,000 | 3,000 |
| Tinplate mills | 2 | 3,000 | 1,500 |

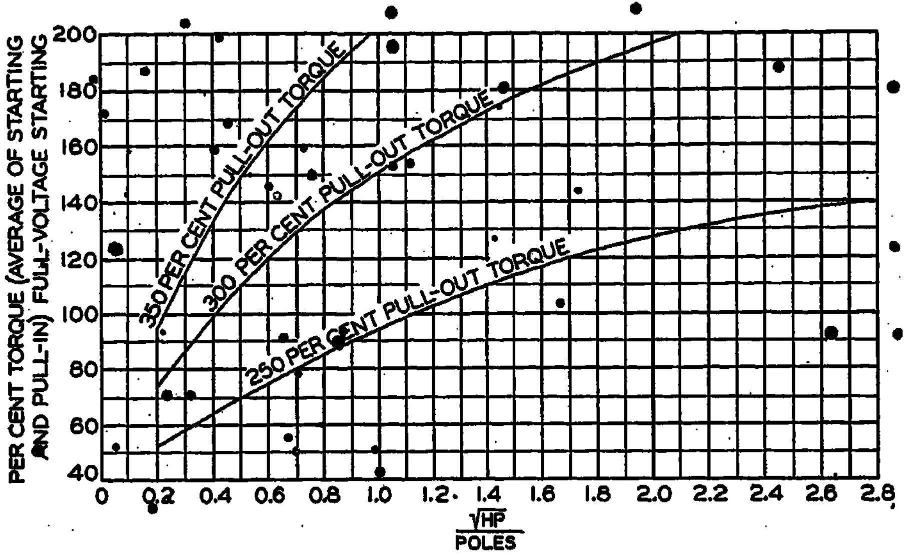

Fig. 1. Approximate relationship of starting and pull-in torque to motor horsepower, speed, and pull-out torque ratings for 60-cycle synchronous motors operating at 0.8 power factor and at speeds of 450 rpm or lower

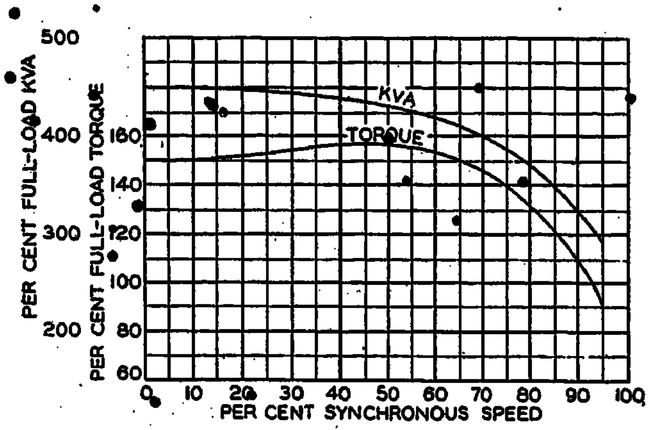

Fig. 2. Starting torque and kva curves for 3,000-hp, 450-rpm, 60-cycle synchronous motors operating at 0.8 power factor (calculated values)

rating, and pull-out torque for which any individual motor is designed. For purposes of illustration, the relations for motors of 0.8 power factor are shown approximately by the empirical curves of Fig. 1. These curves are for 60 cycles, and speeds of 450 rpm and lower. For 25-cycle motors the approximate relationship of starting and pull-in torque to motor horsepower, speed, and pull-out rating, can be derived from Fig. 1, for 0.8 power factor, by multiplying the 25-cycle motor horsepower by 2.4 to locate the desired point on the abscissa.

As illustrated by Fig. 1, an average of starting and pull-in torque in excess of 100 per cent is available inherently over a wide range of horsepowers and speeds, especially for higher values of pull-out torque. For low 60-cycle speeds, where full-load starting torques are not inherent in a normal design, they can be secured by increasing or changing the proportions of active material in the motor. Moreover in all cases, considerable latitude exists in the design of the induction-motor characteristics of the synchronous motor, so that individual values of starting torque and pull-in torque can be varied from the average to provide a torque curve most suitable to meet the requirements of main-roll drives. Pull-out torque requirements for main-roll drive can be secured more easily and less expensively in synchronous motors designed for operation at 0.8 power factor than in those designed for operation at unity power factor. From the standpoint of pull-out torque, therefore, motors operating at 0.8 power factor are preferable.

"Field-forcing" for increasing the field excitation to values above nominal to provide higher pull-out torque during the periods of peak loads, has interesting possibilities in providing for more economical applications on mills with high, but relatively infrequent peak loads. At present, so far as is known, its use is limited because of limitations in the quickness of response to sudden load increases. It is applicable now to drives where increase in load is comparatively slow, or where the load increase can be anticipated either by the mill operator or by trip switches actuated by the metal entering the mill.

8-stand tinplate mill. 2,000-hp 300-rpm synchronous motor

10-stand cold-roll sheet mill. 500-hp 514-rpm motor

Seamless tube mill rolling pipe of approximately 10-in. diameter. 1,500-hp 86-rpm motor

Fig. 3. Kilowatt charts showing nature of power demand met by various synchronous motors

Under normal conditions of starting, except for cold-roll drives, the torques required to break the mill from rest and accelerate it usually are available with a power inrush not exceeding 175 per cent of the full-load kva of the synchronous motor, secured by using one of the various methods of reduced-kva starting. For emergency starting and reversing, where starting torques higher than normal are necessary, the power inrush, of course, will be larger.

The kva starting demand of a synchronous motor, particularly in the larger mills, has become a factor of less critical importance than formerly. As a result, starting at full voltage, with attendant high kva inrush, can be tolerated in many instances to simplify both the starting operation and the starting equipment.

Starting characteristics of a 3,000-hp, 450-rpm, 0.8-power-factor, 60-cycle, main-roll synchronous motor are shown in Fig. 2. A starting torque of 150 per cent, with a starting kva of 450 per cent, is obtained with full-voltage starting. However, a starting torque of 50 per cent normally is ample for starting the mill and with this torque the starting kva is but 150 per cent of full load kva.

In the application of a synchronous motor to a main-roll drive, the inherent characteristics of the motor are such that several factors each must be considered individually. Although in this article an attempt has been made to set forth the general requirements, they should not be considered as ready-made rules which can simply be lifted out and used; good application engineering, with due recognition of the motor's shortcomings, is required at all times. In every case the motor must be designed and built with quite an exact advance knowledge of the mill requirements, necessitating close cooperation between engineers of the mill and of the motor manufacturer.

## NOTES ON TABLE II

1. Types of mills listed are those which afford opportunity for synchronous motor drive, and in general they are the types most frequently used.
2. Motor horsepower and speed limits are approximate.
3. See kilowatt charts of Fig. 3 for graphical depiction of load characteristics for some of these mills.
4. Torques are given as a percentage of the full load torque of the motor, and are based on the average horsepower required for the type of mill. Increase or decrease in horsepower will modify the torque percentages. Torques shown above apply regardless of type of starting used.
5. Lower values of starting torque shown usually are ample to start the mill unloaded, but the higher torques shown must be available.
6. Both 3-high, and continuous billet and bar mills offer suitable and advantageous applications for synchronous motor drives; many such mills now are so driven. Because of the relatively limited, large sections rolled by these mills, speed flexibility usually is not of primary importance, and a constant speed drive is satisfactory.
7. For the roughing and intermediate stands of skelp, hot-strip, merchant, and rod mills, where the metal section is large and the rolling speed relatively slow, a constant speed drive generally is satisfactory and synchronous motors are applied to advantage. For the finishing stands, where the metal section becomes light, and elongation is rapid, adjustable speed motors usually are necessary.
8. Plate mills constitute somewhat of a border line case for synchronous motor application because of the high, short peaks encountered. Conditions permitting, the synchronous motor should prove an advantageous drive, particularly because its use would eliminate speed variation as a deterrent factor in controlling uniformity of gage in rolling. For the roughing and shaping stands used in rolling rails and structural shapes, synchronous motor drive is subject to the limitations imposed by high, relatively short load peaks. For the finishing stands, however, where constant speed is satisfactory, synchronous motor drive is quite suitable.
9. The severe loads imposed by sheet and tinplate mills (of the non-continuous type) are made up of heavy impacts of short duration while the sheet-bars are being broken down, and heavy drags of longer duration when the sheets are being finish-rolled. The largely unrelated operation of the various mill stands results in irregular loads wherein the ratio of average horsepower demand to peak demand may be quite high. Synchronous motors show attractive possibilities of effecting substantial economies and improvements in production when applied to sheet and tinplate mills to replace present induction motors. The constant rolling speed afforded by the synchronous motor is of particular importance in insuring greater uniformity of gage in rolling thin sheets, and in eliminating variable speed as a factor in controlling mill production.
10. Cold-roll sheet mills also provide an attractive application for synchronous motor drives. The high friction load, together with the diversity of operation incident to the use of a single motor to drive several individually fed mill-stands, results in regular load and high load factor. High load factor enhances the economies of the high efficiency operation of the synchronous motor.
11. The load characteristics imposed by mills for making seamless tubes are somewhat alike. As the metal enters the mill, the load rises at once to its full value, remains almost constant at full value for the duration of the pass, then drops back immediately to no-load value. These passes vary in length from approximately 5 to 20 sec and are repeated from 2 to 4 times per minute. Except in the case of certain expanding mills and some reeling mills, a single

| Skelp,[7] hot strip, merchant, and rod mills | Continuous | 1,000 to 7,000 | 80 to 600 | Direct drive, single reduction gear, or tandem gear set | Varying load, moderate peaks | 50 to 100 | 40 | 225 to 300 |
| Plate,[8] rail, and structural mills | Three-high | 1,000 to 7,000 | 80 to 600 | Direct drive, or single reduction gear | Intermittent loads, approx. 1 to 15 sec duration; high peaks | 50 to 100 | 40 | 250 to 350 |
| Sheet and tinplate mills[9] | Two-high trains | 1,000 to 3,000 | 240 to 450 | Single reduction gear | Continuous, irregular load, frequent high peaks | 50 to 100 | 40 | 300 to 450 |
| Cold-roll sheet mills[10] | Two-high trains | 500 to 750 | 240 to 450 | Single reduction gear | Continuous, regular load | 150 to 200 | 100 to 150 | 250 |
| Seamless tube piercing mill | Mannesmann or Stiefel | 1,000 to 5,000 | 150 to 250 | Direct drive, or single reduction gear | Intermittent loads, approx. 6 to 30 sec duration; high peaks. On rolling mills load duration may not be more than 3 to 4 sec. | 50 to 100 | 40 | 250 to 350 |
| Rolling mills | Two-high | 1,000 to 2,000 | 62 to 83 | Direct drive | | | | |
| Reeling, sizing, and sinking mills | Two-high | 350 to 600 | 450 to 600 | Single reduction gear | Intermittent loads, approx. 6 to 30 sec duration; peaks moderate | | ... | 250 to 300 |
| **Copper, Brass, and Other Non-Ferrous Mills** | | | | | | | | |
| Breakdown mills[12] | Two- or three-high | 300 to 1,500 | 250 to 450 | Single reduction gear | Intermittent loads, approx. 1 to 15 sec duration; peaks moderate | 50 to 100 | 40 | 250 |
| Finishing mills | Two- or three-high | 250 to 600 | 250 to 450 | Single reduction gear | Intermittent loads, approx. 5 to 15 sec duration; peaks moderate | 50 to 100 | 40 | 250 |

speed drive is sufficient and the absolutely constant speed provided by the synchronous motor even at high overloads is a factor of considerable importance in making the tube. Also, the first cost and the high power factor and high efficiency at the comparatively slow speeds of these mills have caused the synchronous motor to be used widely for seamless tube mill drive.

12. Synchronous motors have been quite widely applied to non-ferrous breakdown and finishing mills. The power factor correction obtained for synchronous motors is of considerable importance in some plants, offsetting the low power factor characteristics of the induction furnaces used for melting.

# Thermal Transients and Oil Demands in Cables

**Simplified solutions now may be obtained for the thermal transients and oil demands in power cables, due to load variations of any complexity whatever. Mathematical and graphical aids have been developed which greatly reduce the time and labor required for numerical work, and the theory has been verified by measurements on actual cables of the ordinary and oil filled types.**

By
K. W. MILLER
MEMBER A.I.E.E.

F. O. WOLLASTON
ASSOCIATE A.I.E.E.
Commonwealth Edison Company, Chicago, Ill.

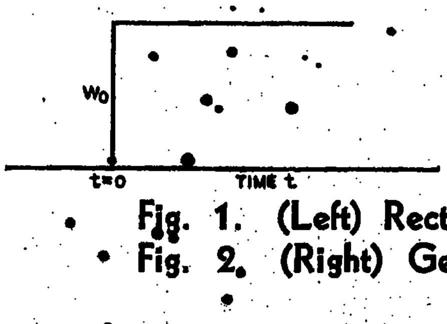
SINCE underground power cables almost always operate under variable loading, it is desirable to be able to establish their allowable carrying-capacities on the basis of variable loading, rather than on the basis of some equivalent steady state loading, as is the present practise. For this purpose it is most useful to know what temperature variations will occur at any point in the cable at any time due to an abrupt change from one constant load to another. Any load curve then can be handled with sufficient accuracy by breaking it up into a series of rectangular steps, and adding with proper time intervals the successive thermal transients.

The fundamental equations were developed several years ago, but the numerical solution was too complicated and laborious to be of general practical value. A simplified method is presented here, which employs calculating charts and other devices permitting complete exact solutions to be obtained in less than 20 per cent of the time formerly required. In addition to temperature transients due to abrupt load changes, precise simplified solutions for the following related phenomena are given:

1. Oil demands due to abrupt load changes in oil filled cables

2. Temperature transients and oil demands due to load variations of any kind, whether abrupt or otherwise.

Although the methods described in this paper were developed for problems of single conductor cables, they can also be applied directly to 3-conductor cables, using a per phase basis (*e.g.*, sheath thermal resistance = $3E$, etc.). For 3-conductor oil filled shielded cable with round conductors, the accuracy will be excellent. If the conductors are sector-shaped, good accuracy may be obtained by using the equivalent round conductors. For ordinary 3-conductor cable with solid fillers and no shielding, the accuracy will be only fair.



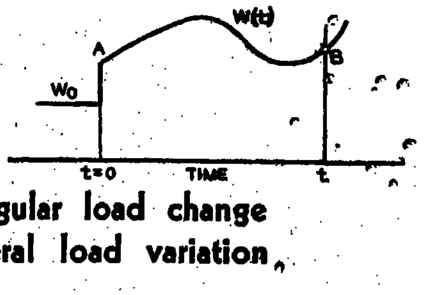


Fig. 1. (Left) Rectangular load change
Fig. 2. (Right) General load variation

---

Based upon "Thermal Transients and Oil Demands in Cables" (No. 32-127) presented at the A.I.E.E. Middle Eastern District meeting, Baltimore, Md., October 10-13, 1932.

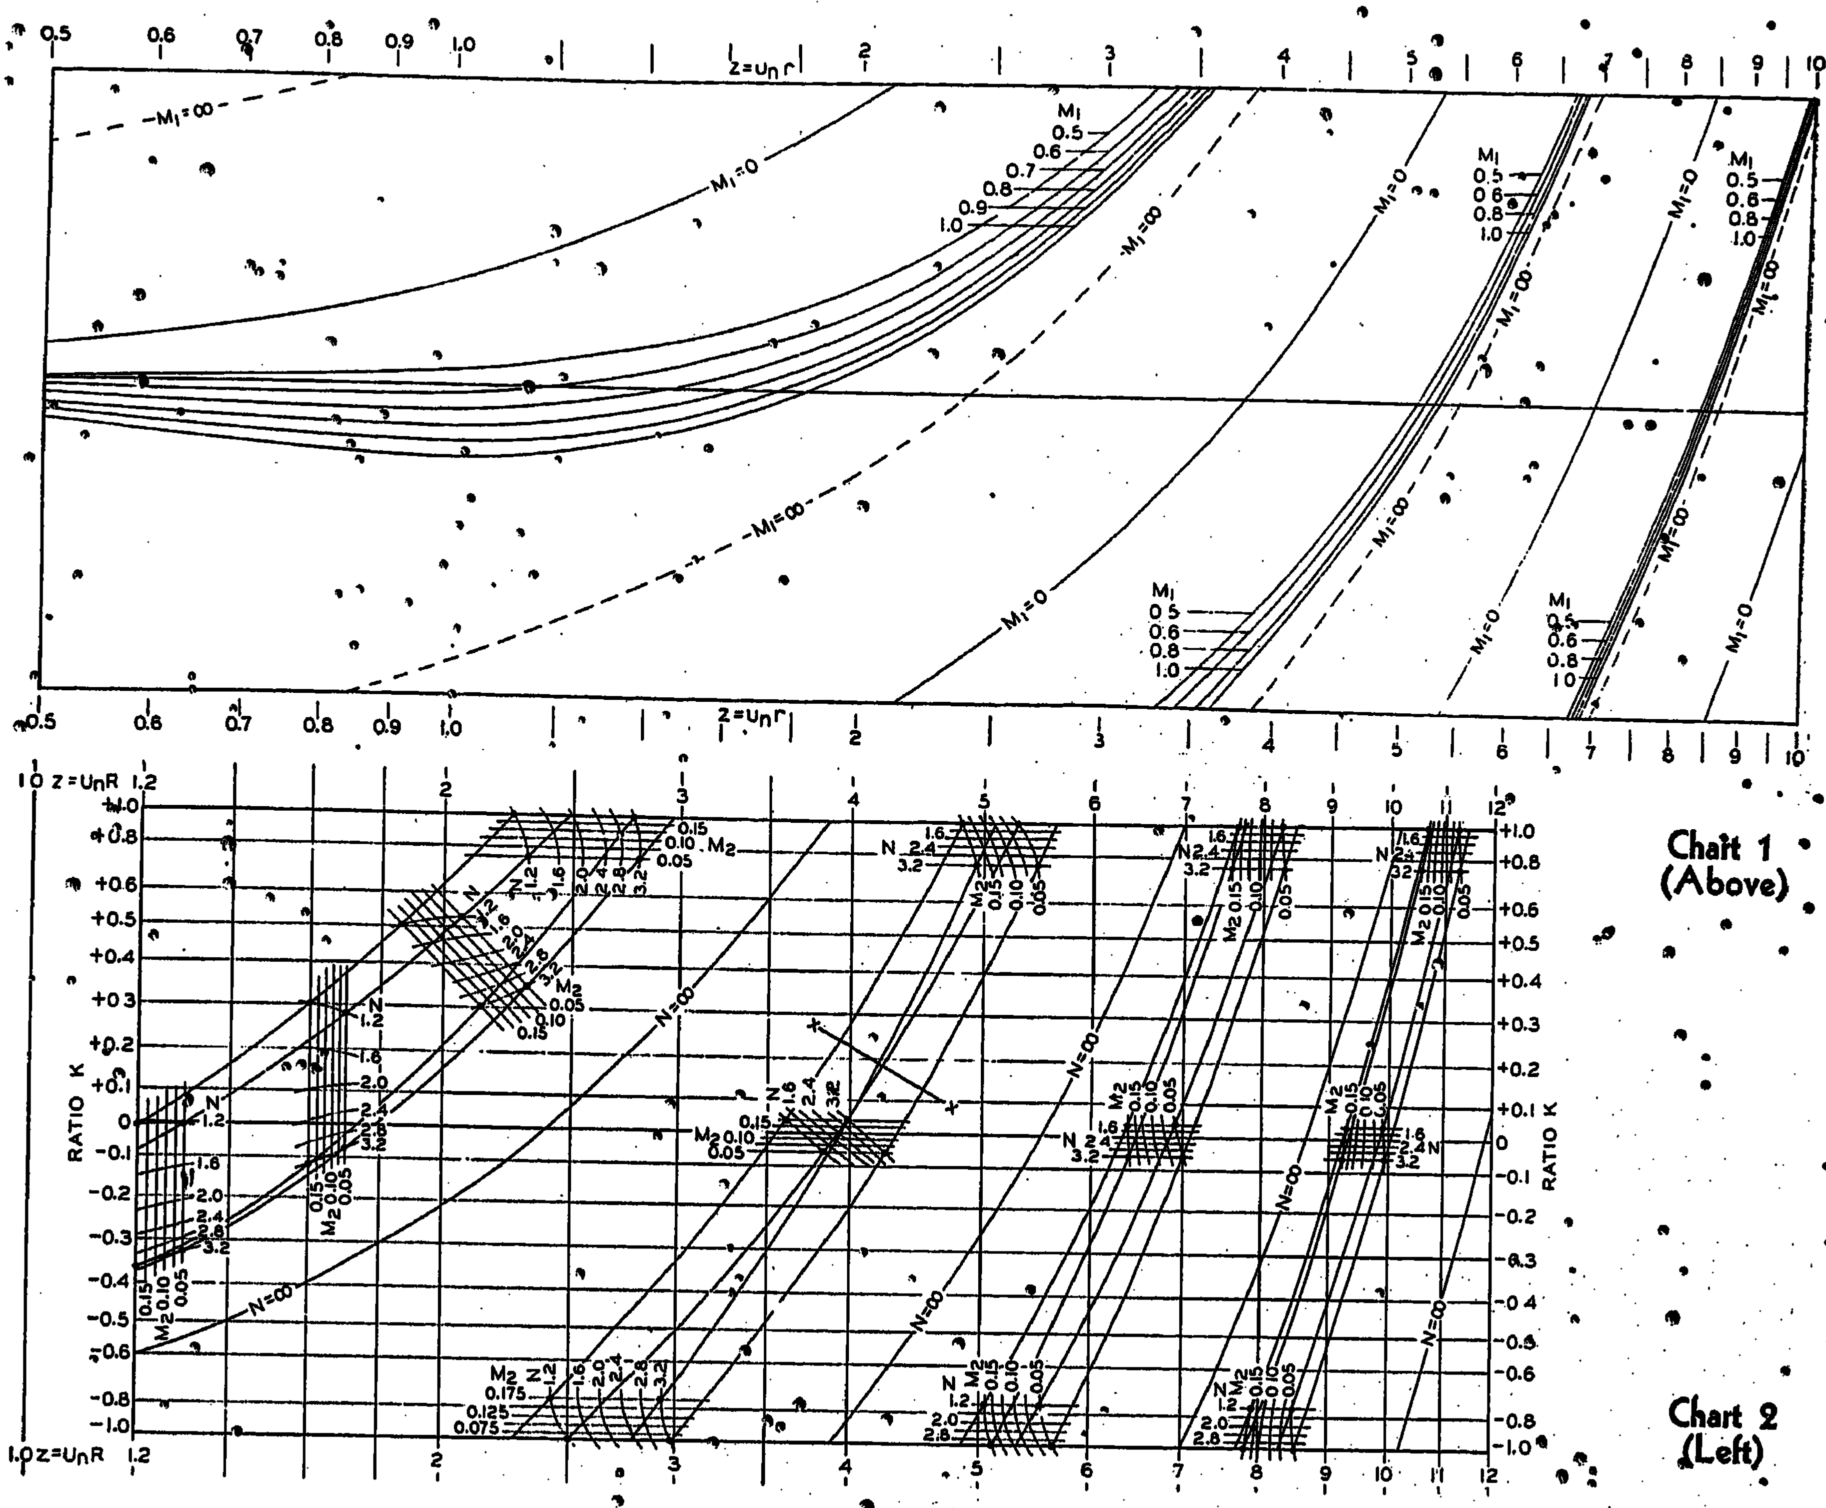

Chart 1 (Above)

Chart 2 (Left)

## SOLUTION FOR ABRUPT LOAD CHANGE

For any abrupt load change such as illustrated in Fig. 1 the equation for the temperature at any point $x$ in the cable at any time is:

$$T = \sum^{n} e^{-\lambda_n t} C_n F_o (u_n x, K_n) + \frac{W_c''p}{2\pi} \log \frac{R}{x} + \frac{W_i''p}{4\pi \log \frac{R}{r}} \left(\log \frac{R}{x}\right)\left(\log \frac{Rx}{r^2}\right) + (W_c'' + W_i'' + W_s'') E + T_o \tag{1}$$

where $\lambda_n = u_n^2/pq$

(For notation see List of Symbols)

For conductor temperature, $x$ is replaced by $r$, and for sheath temperature by $R$. The component oil demands contributed by shrinkage of the conductor, sheath, and insulation are, respectively:

$$a_1 = \frac{Cc}{pq} \sum^{n} u_n^2 e^{-\lambda_n t} C_n F_o (u_n r, K_n) \tag{2}$$

$$a_2 = \frac{Vv}{pq} \sum^{n} u_n^2 e^{-\lambda_n t} C_n F_o (u_n R, K_n) \tag{3}$$

$$a_3 = \frac{2\pi\epsilon}{pq} \sum^{n} e^{-\lambda_n t} C_n [F_1 (u_n R, K_n) - F_1 (u_n r, K_n)] \tag{4}$$

### Instructions for Using Charts 1 and 2

1. Lay Chart 2 over Chart 1 so that the Z axes coincide, and Z = R/r on Chart 2 coincides with Z = 1 on Chart 1.
2. Interpolate on Chart 1 the sequence of curves for $M_1$ and interpolate on Chart 2 the sequence of curves for $M_2$, N.
3. Note the points where intersections occur between the interpolated curves of Charts 1 and 2. Three intersections are sufficient.
4. For the n points of intersection, read off $K_n$ from the vertical scale. Also read off $Ru_n$ and $ru_n$ from the horizontal scales of Charts 2 and 1, respectively, starting at the left.

Note: In printed copy where Chart 2 is not transparent or removal permitted, it is convenient to trace the z axis, the interpolated P curve for desired value of $M_1$ and sufficient identifying abscissas z from Chart 1, on transparent paper, and to lay this tracing over Chart 2 with proper horizontal shift R/r (to the right), after which intersections may be found as already described.

and the total oil demand is:

$$a = (a_1 - a_2 + a_3)$$

The values of $u_n$ and $K_n$ are obtained from $n$ successive intersections (3 are generally sufficient) of the curves of Charts 1 and 2, which are entered

## Table I—Properties of Cable Materials

| Material | Specific Gravity | Weight lb/cu in. | Joules/cu cm/°C | Joules/cu in./°C | Joules/lb/°C | Thermal Resistivity °C/watt/cu cm |
|---|---|---|---|---|---|---|
| Water | 1.00 | 0.0361 | 4.18 | 68.6 | 1900 | 171 |
| Copper | 8.95 | 0.3230 | 3.44 | 56.4 | 175 | 0.285 |
| Lead | 11.37 | 0.4110 | 1.43 | 23.4 | 57 | 2.990 |
| Transformer oil | 0.90 | 0.0325 | 1.90 | 31.1 | 957 | 611 |
| Dry paper | 1.41 | 0.0508 | 2.26 | 37.1 | 730 | 770 |
| Oil filled insulation | 1.15 | 0.0415 | 2.10 | 34.5 | 832 | 550 |

The weight of copper conductor is 3.15 lb and its thermal capacity 551 joules per deg C per circular-inch foot, as ordinarily stranded and cabled.
The weight of lead sheath is 15.5 *Dd* lb and its thermal capacity is 883 *Dd* joules per deg C per ft, where *D* and *d* are the average diameter and thickness in inches.

with values of $M_1 = \frac{Q_1}{2\pi q r^2}$, $M_2 = \frac{Q_2}{2\pi q R^2}$, $N = \frac{p}{2\pi E}$, and $\frac{R}{r}$. The functions $F_o(u_n x, K_n)$ are obtained from Chart 3. The functions $F_1(u_n x, K_n)$ are obtained from Chart 4. Values of $C_n$ are obtained from the following equation:

$$\sum^{n} - C_n F_o(u_n x, K_n) = \Delta W_c \frac{p}{2\pi} \log \frac{R}{x} + \Delta W_i \frac{p \left(\log \frac{R}{x}\right)\left(\log \frac{Rx}{r^2}\right)}{4\pi \log \frac{R}{r}} + (\Delta W_c + \Delta W_i + \Delta W_s)E$$

by evaluating all terms except $C_n$ for $n$ different values of $x$, and solving the resulting simultaneous equations. Values of $C_n$ should be calculated for unit change in copper loss, dielectric loss, and sheath loss separately. Eq 1, 2, 3, and 4 will then yield "unit" transients. These need be calculated only once for a given cable, since for any particular problem the unit transients can be proportioned and added together in any ratio and combination desired, which is the work of but a few minutes. All quantities, such as $p$, $q$, $R$, $W_o$, $c$, etc., in the expressions for temperature and oil flow transients are readily obtained from Table I, or by well known methods which require no explanation.

The oil flows obtained from eq 2, 3, and 4 will be slightly in error for the first few moments of the transient, because only a few terms in the infinite series are used in obtaining numerical values, and the neglected terms are appreciable when $t$ is very small. The following correct expressions should be used for the initial instant ($t = 0$):

$$a_1 = -\Delta W_c \frac{Cc}{Q_1} \quad a_2 = -\Delta W_s \frac{Vv}{Q_2} \quad a_3 = -\Delta W_i \frac{\epsilon}{q}$$

### Solution for General Loading

The rectangular solution is readily generalized almost by inspection, through a well known application of the superposition principle. For the entirely general load curve of Fig. 2, the general solution for temperature at any point $x$ is:

$$T = \sum^{n} C_n F_o(u_n x, K_n) L_n(W, t) + (W_c)_t \frac{p}{2\pi} \log \frac{R}{x} + (W_i)_t \frac{p}{4\pi \log \frac{R}{r}} \left(\log \frac{R}{x}\right)\left(\log \frac{Rx}{r^2}\right) + E(W_c + W_i + W_s)_t + T_a \qquad (5)$$

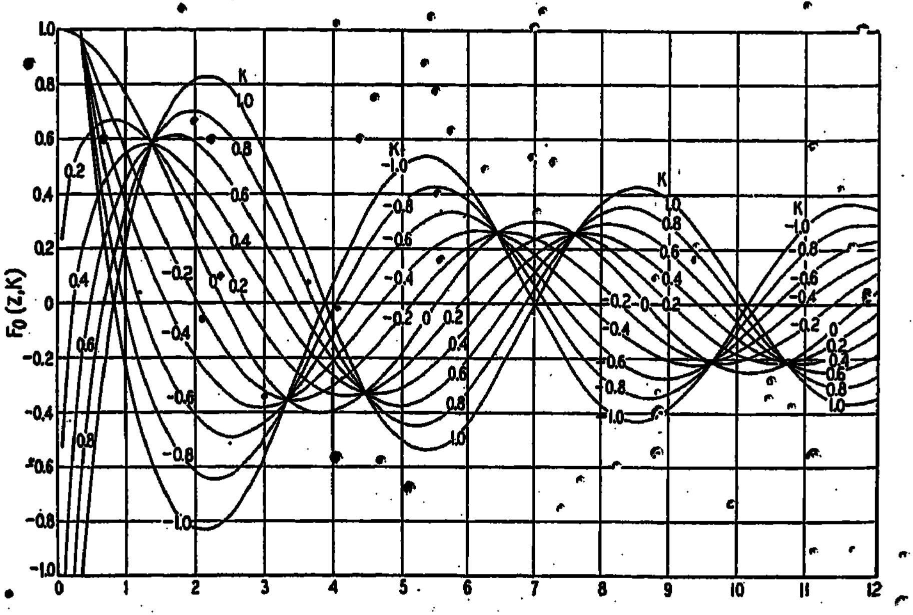

Chart 3. Functions F₀

The generalized oil flow equations are similarly obtained by substituting $L_n(W, t)$ for $e^{-\lambda_n t}$ in eq 2, 3, and 4.

The last 4 terms in the above equation differ from the corresponding terms in the rectangular solution only in that instead of using the constant watts lost after the transient, indicated by the superscript ($''$), the variable watts loss during the transient, indicated by subscript ($t$), is used, as explained below. The summation term is identical with the corresponding term in the rectangular solution, except that $L_n(W, t)$ is substituted for $e^{-\lambda_n t}$. The load function $L(W, t)$ is known as the Duhamel Integral, and for the present purpose is as follows:

$$L_n(W, t) = \left[\lambda_n e^{-\lambda_n t} \int_o^t (W_t - W_o) e^{\lambda_n t} dt - (W_t - W_o)\right]$$

Where the losses $(W)_t$ can be expressed as a mathematical function of $t$, the integral can be formally evaluated. For practical load curves this is seldom the case, and graphical or step-by-step methods must be employed. For the step-by-step method the load function is easy to evaluate when rewritten in the following approximate form:

$$L_n(W, t) = \left[\lambda_n \Delta t e^{-\lambda_n t} \sum_{0}^{t} e^{-\frac{W_t - W_o}{\lambda_n t}} - (W_t - W_o\right] \qquad (6)$$

The expression under the summation sign is to be evaluated point by point up to time $t$ (or point $B$, Fig. 2), using equal finite intervals of time $\Delta t$ for the preceding period. For good accuracy, $\lambda_n \Delta t$ should not exceed 0.5, and it is best to use the average values of $(W)_t$ and $t$ for each increment term under the summation sign. $\lambda_n$ and $C_n$ are exactly the same as for the rectangular solution.

At the instant of an abrupt discontinuity in $(W)$, the values of $L(W, t)$ for use in temperature equations are:

$$\Delta L_{cn} = -\Delta W_c \qquad \Delta L_{in} = -\Delta W_i \qquad \Delta L_{sn} = -\Delta W_s$$

and for oil flow equations, the correct values of oil flow are calculated directly from:

$$\Delta a_1 = -\Delta W_c \frac{Cc}{Q_1} \qquad \Delta a_2 = -\Delta W_s \frac{Vv}{Q_2} \qquad \Delta a_3 = -\Delta W_i \frac{\epsilon}{q}$$

for the same reasons discussed in connection with the solution for rectangular load change.

## PRESSURE DISTRIBUTION IN INSULATION

The principal object or purpose of oil filled cable is the prevention of free gas spaces or open voids in the insulation. One of the chief causes of formation of such voids is the thermal shrinkage of the oil during decreases in cable loading. With the complete solution of the thermal transient available, a thorough investigation can be made of the possibility of this happening from an oil pressure standpoint for any assumed load conditions.

The pressure drop across the wall of insulation depends on the resistance of the paper tapes to radial oil flow. The insulation of commercial cables is often arranged in zones, the density of the tapes being different for each zone. It is necessary to know the dimensions of these zones, and their respective coefficients of friction to radial oil flow. Actual values for the latter have been found to range from 50 to 500 near the sheath, and 400 to 1,000 near the conductor, the units being (lb per sq in.) per (in. cube) per (cu in. of oil per hr) for oil having a viscosity of 50 centipoises.

The process of solution for the radial pressure drop due to a rectangular load change is sufficiently illustrated in Fig. 3. In part 2, $a_3$ is obtained from eq 4 by replacing $r$ by $x$ if oil feed is from a hollow core only; for feed from sheath channels only, $x$ replaces $R$. For general load variation the generalized form of the rectangular solution should be used. The calculated pressures, part 4, must of course be altered by an additive constant for hydrostatic pressure so as to make the pressure at the inside (or outside) radius of the insulation equal to the pressure in the oil core (or sheath) at the moment under consideration. If the final resultant pressure is anywhere less than the partial pressure of solution of gases absorbed in the oil, then presumably voids will form.

Following the procedure outlined, a graphical solution of the radial pressure drop was computed for one of the oil filled cables installed in Chicago. Under the most severe conditions of dropping load in the winter, the radial pressure drop was only a fraction of a pound per square inch, or much less than the minimum permissible oil pressure in the core. In the present design of oil filled cables, the radial oil pressure drop is insignificant because of the small viscosity of the oil. However, in solid cables with thick compound this is not so, and the type of analysis given above is useful in determining internal pressures and vacuums developed during load variations.

## VERIFICATION BY FIELD AND LABORATORY TESTS

The theoretical methods have been found to give results in close agreement with actual measurements in every case which has been checked. For example, the curve of Fig. 4 was selected at random from a series of tests made at the University of Wisconsin. The calculated points are shown by the circles. The agreement between calculated and test

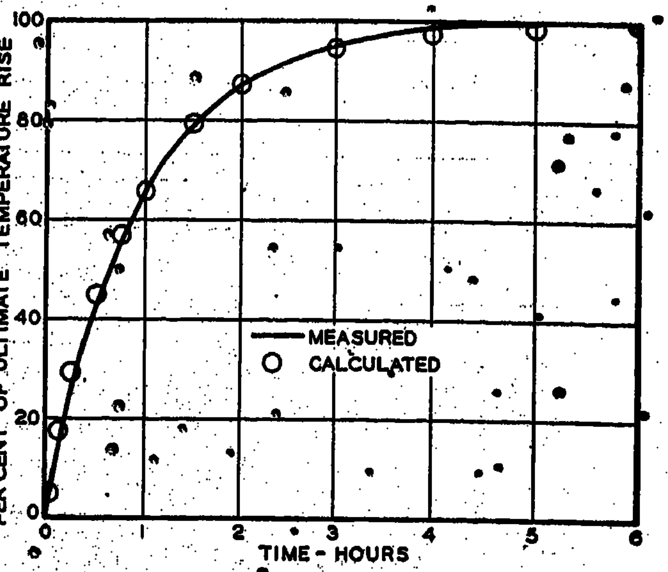
**Fig. 4. (Right) Copper temperature transient due to abrupt change in copper losses**

Single-conductor 500,000-cm cable having 26/64 in. ordinary insulation and 7/64 in. lead sheath



values is almost perfect except for the latter part of the transient. The disagreement is due to the fact that in the test, the heating current was kept constant. This resulted in a continuous slight increase in the conductor losses, due to the rising conductor temperature. It was not thought worth while to include a correction for this residual effect in the calculations, which are based on the assumption that the conductor loss remains constant after the transient is initiated (see Fig. 1). The last few calculated points, therefore, fall slightly below the test points.

Field tests in Chicago on 2 132-kv oil filled lines provided an opportunity of testing the theory from every angle. In the field tests, a heavy load (200,000 kva in one case) was suddenly thrown on the line, maintained as nearly constant as practicable for several hours, and then suddenly switched off. Records were obtained of conductor current, volumes of oil in feeding reservoirs, and oil pressures at various locations along the line.

The tests were entirely reconstructed by theory, the only known factors being the constants of the cable, the loads employed, and the duct temperature. The results are shown in Tables II and III. Table II provides a check of the slope of the temperature transient curve, as well as of oil flows, since the oil flow depends upon the rate of change of temperature. The agreement is good, and most of the error probably lies in the measured values, since the type of oil reservoirs used made it impossible to obtain precise oil volume measurements. Table III provides a check of the actual cable temperatures as well as of oil pressures, since the pressures depend on the oil viscosity and therefore on the cable temperature. The close agreement between measurement and calculation in Table III is a further indication that the calculated values of Table II are more precise than the measured values. An unavoidable error was, of course, introduced in all the calculations by the necessity of assuming that the duct temperature was the same throughout the length of the cable. Actually the duct temperature probably varied considerably from manhole to manhole.

## CONCLUSIONS

1. A simple solution has been obtained for cable transients due to a rectangular load change. The theory has been verified by measurements on actual cables of the ordinary and oil filled types.

2. Mathematical and graphical aids have been developed which greatly reduce the time and labor required for numerical work. Solution and verification of a complete problem formerly required about a week. With the aid of the new methods, the same results can now be obtained in one day.

3. The transients due to load variations of any complexity whatever have been solved by using the well known superposition theorem. Any desired degree of accuracy can be obtained.

4. The duct temperature transient is of importance in problems of variable loading, but has not been adequately investigated. Further work should be done along this line.

5. Some of the constants needed for use in thermal and oil flow problems of cable insulation are relatively new. Many of the values now in use for these constants are based on only a few scattered observations. Further laboratory and field data should be obtained.

## LIST OF SYMBOLS

$t$ = time in second
$r$ = inside radius of insulation
$R$ = outside radius of insulation
$x$ = radius of cylindrical element considered
$Q_1$ = total thermal capacity of copper conductor and free oil in strands and core (if any) per unit length, Joules/deg C
$Q_2$ = total thermal capacity of sheath, armor, shielding tapes, and free oil in channel or sheath flutes (if any) per unit length
$q$ = specific thermal capacity of insulation, per unit volume
$p$ = specific thermal resistance of insulation, per unit volume
$w$ = dielectric loss per unit volume at unit voltage gradient

* Estimated. Boosters were reconnected at peak pressure.
** Balanced pressure section. Reservoirs disconnected at one end.

$E$ = thermal resistance, sheath to duct, per unit length
$G$ = thermal resistance, copper to sheath, per unit length
$T$ = temperature deg C at point and time considered
$T_o$ = duct temperature
$W$ = watts heat flow across cylindrical element at $x$
$W_c$ = watts copper loss
$W_i$ = watts dielectric loss per unit length of cable
$W_s$ = watts sheath loss
$C$ = total volume copper conductor and free oil per unit length
$V$ = total volume inside of lead sheath or inside of shielding tape, if any
$c$ = effective volumetric thermal coefficient of expansion of copper core and free oil combined, per deg C
$\epsilon$ = effective volumetric thermal coefficient of expansion of insulation, oil and paper combined, per deg C
$v$ = effective volumetric thermal coefficient of expansion of lead sheath, corrected for free oil in channel or sheath flutes, if any
$a_1$ = rate of oil flow contributed by conductor and core, cu cm per sec per unit length

$a_2$ = rate of oil flow contributed by lead sheath shrinkage or expansion, corrected for oil in flutes or channels, if any
$a_3$ = rate of oil flow contributed by insulation
$a$ = total resultant rate of oil flow, per unit length
$\rho$ = resistivity of insulation to radial flow of oil of standard viscosity
$\mu$ = correction applied to $\rho$ to take account of actual viscosity of oil
$\Delta$ = finite increment of quantity considered

Thermal "constants" are assumed independent of temperature

Subscripts $c$, $i$, and $s$ refer to conductor, insulation, and sheath, respectively

Superscript ($'$) indicates conditions before transient

Superscript ($''$) indicates conditions during and after transient

All logarithms are to base e.

# A Rotary Voltmeter

**A new electrostatic voltmeter for measuring either a-c or d-c potentials has been developed; it has a range limited only by its insulation, possesses high accuracy, and draws no current. This article describes the new meter and some of its uses.**

By
PAUL KIRKPATRICK Stanford Univ., Calif.

DESCRIPTIONS of high voltage voltmeters by the dozen may be found sprinkled through the literature of engineering and physics, and in the face of this wealth of invention the proponent of yet a new one feels required to justify his entrance into the well filled field. The defense offered in this case lies precisely in this abundant bibliography and in the thought that these continued and varied efforts strongly suggest a problem still unsolved. Instruments excellent in some respects have generally purchased such excellence by sacrifices in other respects. Highly accurate electrostatic voltmeters acting upon attraction or repulsion principles have been constructed, but unfortunately they are non-portable, non-linear, and dependent upon other meters for their calibrations. Spark gaps are rugged, portable, and simple to construct, but their limitations in other respects are too well known for comment. Wire-wound high resistances of good design, used in conjunction with a galvanometer or potentiometer, are accurate and highly satisfactory to those who can afford them, at least in constant potential applications. In some cases, however, the load which they impose upon the high potential source is undesirable.

The instrument to be described here operates according to principles which are thought to be new in high potential measurements, and accordingly it possesses a set of characteristics not duplicated in other existing meters. Fortunately, practically all of the well-known defects have been avoided, and no new ones have appeared during a testing period of more than a year in routine service, unless the noise produced by the running of a small motor be accounted a defect.

Briefly this is a rugged and portable a-c or d-c voltmeter of unlimited range, high accuracy, short period and linear scale characteristics. It draws no current, has no detectible temperature errors, and is not unreasonably difficult or expensive to construct. The indicating instrument is at earth potential and may be located remote from the rest of the meter. The calibration of this meter inheres in its construction and may be established without recourse to any high potential manipulations whatever.

Central unit of the meter is a contrivance which may be called an electrostatic generator. It has several points of analogy with a simple 2-pole, separately excited electromagnetic d-c generator. In the electrostatic generator a simple armature rotates in the electrostatic field existing between 2 pole pieces whose difference of potential is to be measured. The armature, driven at constant speed by a synchronous motor, generates a direct current which is directly proportional to the potential difference applied to the pole pieces. This generated current is conducted to a suitably calibrated galvanometer or microammeter, from which the value of the applied potential may be read directly. The whole assembly is termed a rotary voltmeter.

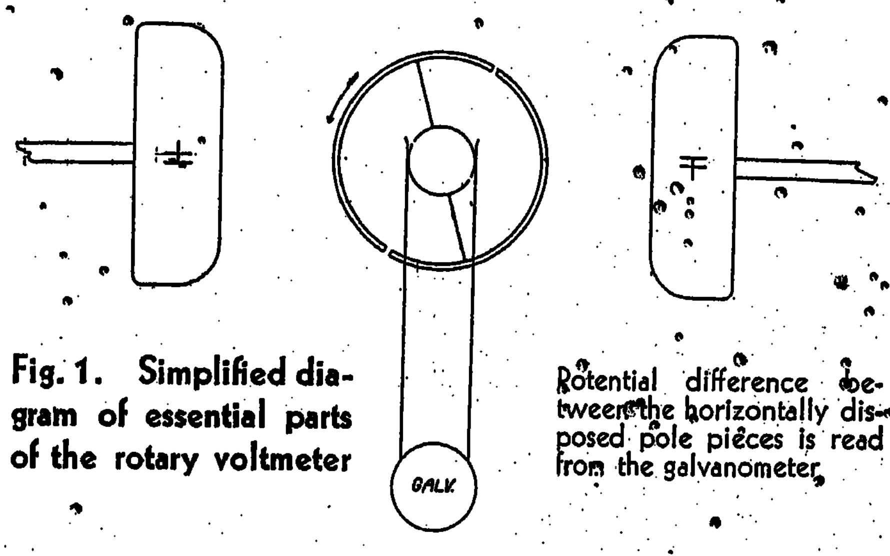

**Fig. 1. Simplified diagram of essential parts of the rotary voltmeter**

Potential difference between the horizontally disposed pole pieces is read from the galvanometer

Essentials of the meter are shown in Fig. 1. The so-called armature is a piece of metal tubing which has been sawed longitudinally into 2 equal semicylinders. These are connected electrically only by the path leading through the commutator and galvanometer. When the meter is in operation, the galvanometer receives a pulsating direct current the average value of which, as shown by simple theory and many experiments, is given by the formula $I = 2CVn$, in which $V$ is the applied potential

---

Prepared especially for ELECTRICAL ENGINEERING. *Not published in pamphlet form.*

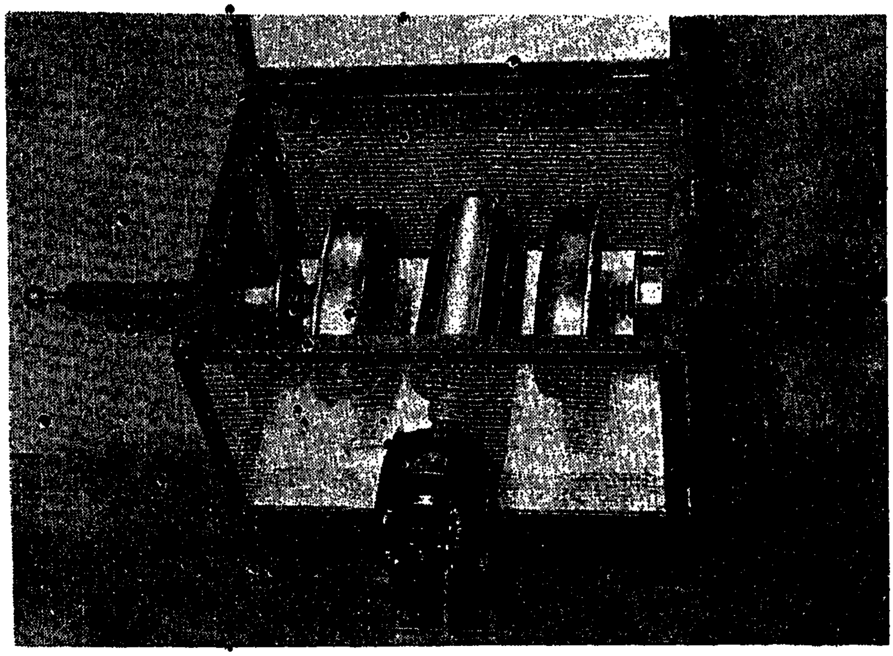

Fig. 2. Rotary voltmeter for measuring potentials from 1 volt to 110 kv; complete except for galvanometer

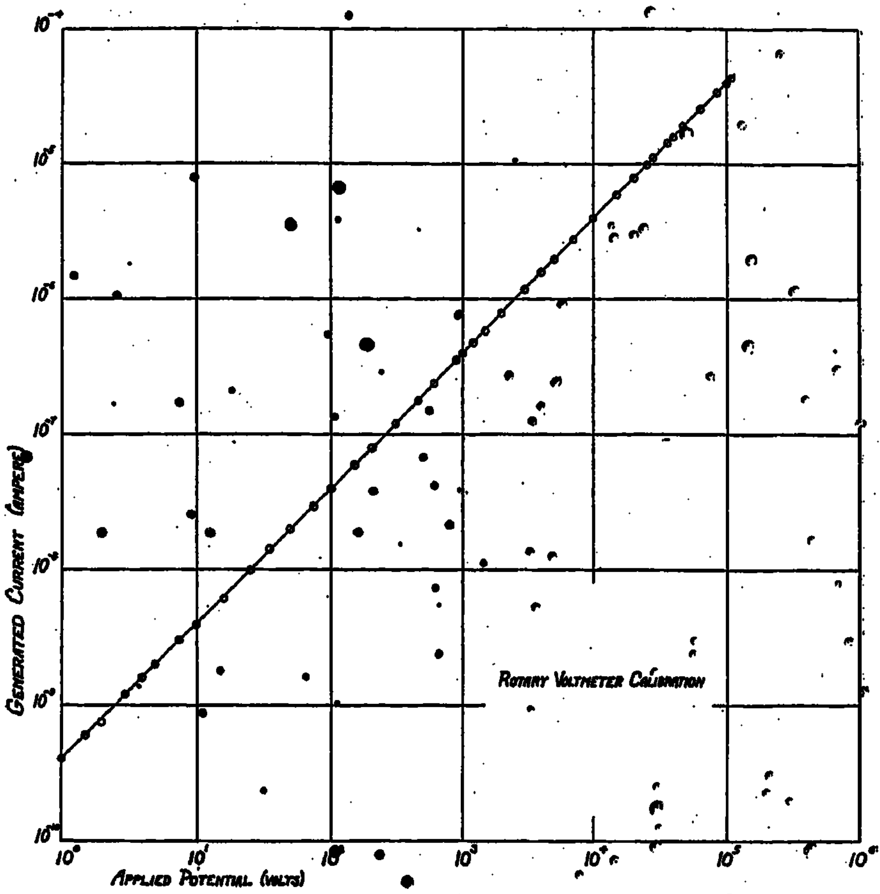

Fig. 3. Experimental calibration curve for the instrument shown in Fig. 2. The curve is straight and agrees with the theoretical equation $I = 2CVn$

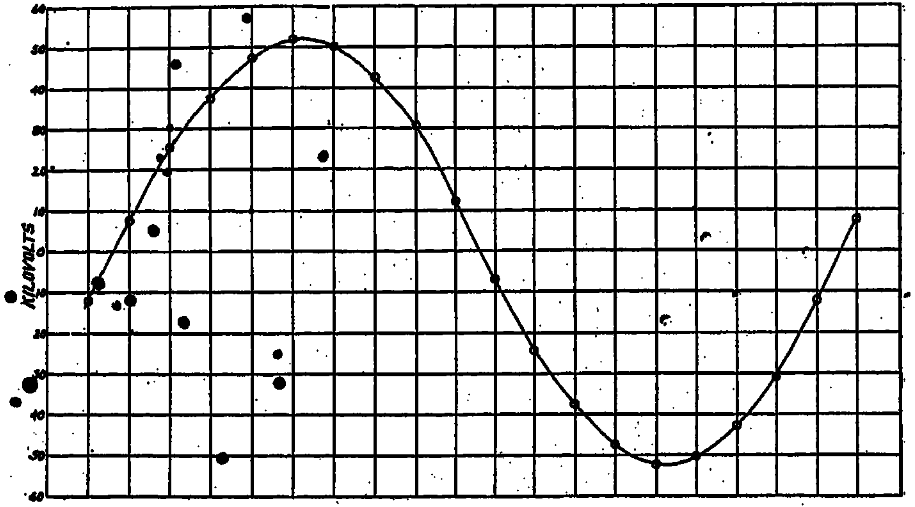

Fig. 4. Potential wave form across the secondary terminals of a high voltage transformer, as determined with the rotary voltmeter

(here supposed constant) $n$ the speed of rotation of the armature in revolutions per second, and $C$ the capacitance of a system comprised of the armature and one pole piece. This equation has been checked exhaustively on 3 different generators, in many cases with all relevant quantities independently measured; it holds rigorously over a wide range of voltage.

The generator shown in Fig. 2 was built for measuring potentials up to 110 kv. The upper limit is set only by the limitations of the insulators and the width of the gaps between the pole pieces and the rotor. The wide range of potentials measurable with this meter and the proportionality existing between potential and generated current over the entire range are displayed by the graph in Fig. 3. The circled points represent corresponding values of independently measured applied potentials and generated currents. Currents such as those designated at the lower end of the graph require a rather sensitive galvanometer for their measurement, but up in the practically useful part of the range a portable microammeter of the pointer type or a switchboard microammeter is perfectly adapted and most convenient.

Calibration constant of a voltmeter of this type may be determined either by applying a known potential of a few hundred volts and measuring the resulting current, or by measuring the capacitance $C$ and taking account of the known speed of rotation. Both methods have been found to be practical and easy and the resulting calibrations to be correct to within a small fraction of one per cent. It is found in most cases that the accuracy of the rotary voltmeter is simply the accuracy of the indicating instrument itself. Calibration methods have been more fully described in another article published in *Review of Scientific Instruments*, v. 3, 1932, p. 430–8.

As mentioned previously, the rotary voltmeter is useful for measuring alternating as well as direct potentials. Close analysis of the generating process shows that the only potential difference of significance in the equation $I = 2CVn$ is the potential difference existing when the semi-cylinders of the rotor are turned directly toward the pole pieces, that is, at the instant of commutation. In other words, the generated current is proportional to the *instantaneous* value of the applied potential at a certain instant during the rotation. If the rotor is driven by a 4-pole synchronous motor connected to the same power system as that which furnishes the potential to be measured, this instantaneous value recurs identically twice in each revolution, that is, at each commutation point. The voltmeter then measures this instantaneous potential, regardless of the potentials that may obtain during other parts of the cycle.

By advancing or retarding the rotor in its synchronous rotation various potentials along the applied voltage wave may be determined in turn and the entire wave form expeditiously plotted in a point-to-point manner. This control of the rotor phase has been accomplished in two ways: by bodily rotating the motor a portion of a revolution about its own axis; and by operating the motor on current from a phase shifting transformer. The latter method, which has the advantages of greater simplicity and convenience, was employed in determining the output wave form (see Fig. 4) of a high voltage transformer.

High potential wave forms for various conditions of rectification, filtration, and load have been determined by this method. When it is desired to measure only the peak value of an alternating potential the rotor phase may be set for the maximum generated current and left in that adjustment. These voltmeters so far have been used only in a few experimental X-ray laboratories; but their dependable and inconspicuous performance in these cases suggests that they will be found useful in a variety of other applications.

# Pneumatic Tired Diesel Electric Rail Car

A DIESEL electric rail car having a body of stainless hi-tensile steel construction and running on pneumatic rubber tires has recently been delivered to the Reading Company. Much fundamental development work in the building of this 47-passenger car was done by the E. G. Budd Manufacturing Company, involving the forming and handling of thin sheets of steel, and requiring considerable research into methods of welding. As the result of this work the weight of a self-propelled car of a given seating capacity has been reduced to 33 per cent of the weight of the accepted passenger coach having no power as used on Class I roads.

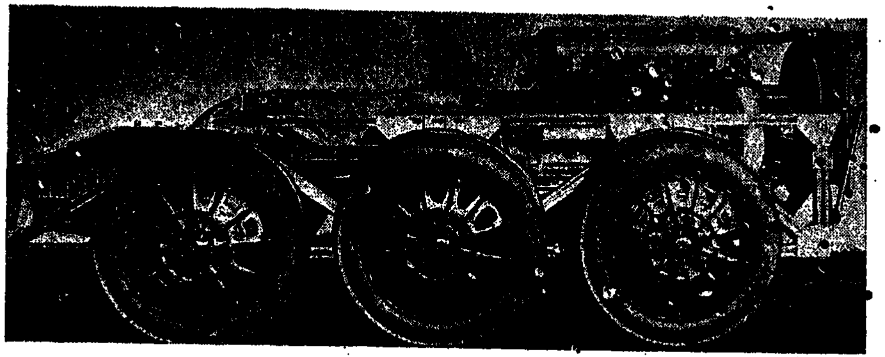
The front or power truck is equipped with a 125-hp Cummings diesel engine directly connected to a Westinghouse 250-volt generator of special light weight construction. In the power truck also are mounted the batteries and control. The rear or traction truck is a single high speed Westinghouse motor mounted under the bolster. The double extended shaft drives the front and rear axles of the traction truck through a Timken differential worm gear having a ratio of 9.1 to 1.

The trucks, of unusual design, are of light weight construction. The power truck has a "shot-welded" stainless steel frame weighing 281 lb, while with the engine, generator, batteries, axles, wheels, etc., the total weight is 6,990 lb. In the traction truck the "shot-welded" stainless steel frame weighs but 230 lb, whereas the motor, axles, wheels, etc., make the total weight 4,315 lb.

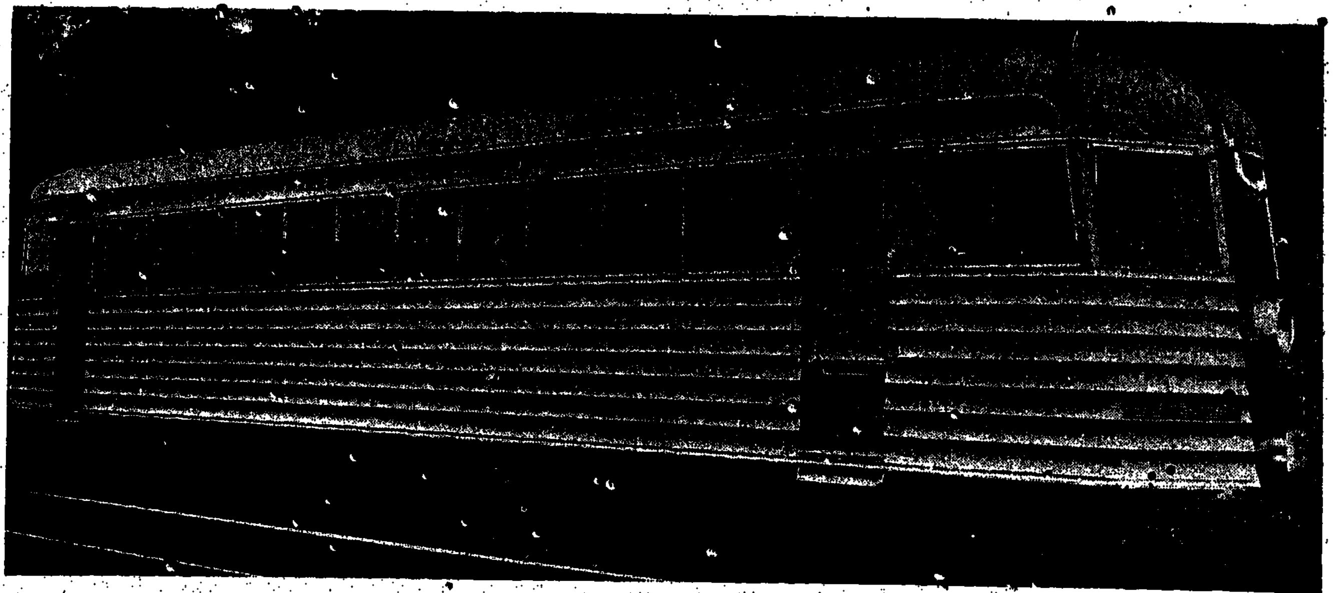
The interior of the car is of extremely simple design, the vestibule being free of any obstruction from the engine. Lighting receptacles are recessed on either side of the exhaust ventilating duct which runs along the center of the car, resulting in a very pleasing and efficient scheme of indirect lighting.

The windows are permanently closed, keeping out the dirt and much of the noise. An ingenious ventilating system takes in air on either side of the car at the step wall and by a motor operated fan distributes it along either side of the car. In winter the air is drawn through a radiator heated by water from the engine. The air is then distributed by conduits evenly through the car. A radical design of reversible seat has been used, the double seat with rubberized hair and leather covering weighing but 50 lb.

Stainless steel marker lights are built neatly into each of the 4 corners of the car. Automatic air engines operate the side doors, trap doors, and folding step, as a unit. The controls of the car are simply arranged for operation from either end of the car.



The front truck of the diesel electric car. This truck carries a 125-hp diesel engine and direct connected 250-volt generator. Batteries and control also are mounted on this truck. The rear truck, not shown, carries the traction motor



Pneumatic tired diesel electric rail car of stainless hi-tensile steel construction. No paint is used on the outside of the car, the stainless steel permitting a permanent luster finish. The car is 51-ft in length, weighs approximately 22,000 lb, and has a speed of from 50 to 55 mph. The tires are 33 x 4½ in., and carry a pressure of 95 lb

Oil pressure, water temperature, and engine speed are all relayed by light circuits.

The rapid acceleration of the car, the riding qualities of the pneumatic tired wheels and the exclusion of noise and dirt combine to give an extremely pleasant reaction to the passenger. When properly applied economies may be secured by this type of high speed light weight self-propelled car which should make it attractive to the railroad operator.

# Usury on Labor

**Too great success in cornering our mediums of production is considered responsible by many for our present industrial instability; the result is usury on labor. This is the fifteenth article in the Engineering Foundation's symposium "Has Man Benefited by Engineering Progress?"**

By
**ROBERTSON MATTHEWS**
Research and Development Engineer, Bolton, Canada

MACHINES now idle that were running 24 hr per day in 1928 and '29, create a situation demanding correction. Not many years ago we had a moneyed class able to aid liberally in the support of education and general culture, with machinery operated 10 hr per day; with better machines running 24 hr our moneyed class has not been able to keep the business ship on an even keel nor to provide those conditions which history shows are usually a preventive of radical measures and social unrest. After 2 or 3 yr with machines manned by shock troops 24 hr per day, we are having more than 2 yr with those machines largely idle. The cause is declared an obscure mystery. What we learn from this mess is going to depend upon what we do about it.

Our sires thrived on the 10-hr day. We have more machines, better machines, a more elaborate organization; and in many lines we are overtooled.
commodity appears to be attractive
many rush to make it. Where
ble, 24-hr operation is taken as
system capital thus leads
ng like an engine without a governor; but systems, like engines, can destroy themselves if ungoverned.

Now we know (after being forced to learn) that long hours of labor per shift are not best for economic production and social progress. Is it not, therefore, possible that 24-hr operation of machines, though admittedly representing 100 per cent load factor for money invested, has some wide influence which is highly pernicious to business and social harmony? May not more cooperative planning, even internationally, be essential in order to govern the capitalistic engine as now massively and highly developed?

Success in business has too long been significant of predatory characteristics; but has any national organization based upon war and predatory behavior long survived? Why in peace time the pressure of 24-hr operation of machinery? Under what circumstances is it socially permissible? What relation should hours of machine operation per day bear to hours of labor for each shift?

## CORNERING HAS BEEN GOING ON FOR AGES

For ages there have been attempts by some members of a community to corner the prevailing medium of exchange, and to release it for use by other citizens only on prepayment of excessively high interest. This is usury on money, and there are state laws respecting it. Respecting mediums of *production* we still are without proper correctives against cornering. Too great success in cornering our mediums of production, among which labor takes first place, is considered responsible by many for our present industrial instability. Before society can enjoy the activities of labor and benefits from engineering progress, a few persons who are in control demand an over-large portion of the returns for themselves. In short, the result is *usury on labor*.

Social welfare and stability demand, therefore, that all workers shall share in the greater returns from an improved load factor of a manufacturing plant. Should the market warrant 12-hr operation of machinery, then let there be, say, 2 shifts of 6 hr each; if 20-hr operation, 4 shifts of 5-hr each; if 24-hr operation, 6 shifts of 4-hr each, the pay to remain approximately the same *per shift*.

With such pay, employes could better meet the fluctuations in employment likely to occur for some years, until we arrive at a better social-industrial organization. This procedure would offer to all concerned in manufacture an incentive for improving the product and its market. The unequal hours in different industries might draw the better grade of workers to places where the hours were most favorable. This would be placing benefits among those workers most likely to benefit society, and whose betterment would provide opportunity for their higher self-development and culture with more inspiration for their children—social stabilizing conditions such as are becoming eliminated in the present militarized industry with the larger benefits and privileges going to an extreme few at the top.

# Telephone Cables in Large Buildings

**Design of telephone facilities for large buildings requires the careful consideration of a large number of factors to insure that the telephone plant shall be used with the maximum degree of efficiency. The factors which must be considered are outlined in this article, which is a portion of the authors' complete paper on the general subject of cables for telephone distribution.**

PLANNING of telephone facilities for large buildings is a problem which rivals in importance the planning of the telephone distribution system between the central office and the customer's premises. Telephone cables used for distribution within a building are termed "house" cables. Close cooperation is necessary between the telephone engineer and the owner, architect, or contractor in order that the house cable system may be designed to conform to the building layout, and in order that the building plans may include the provision, by the owner, of the necessary shafts, conduit, cabinets, and other housings for that house cable system.

## Building Cable Design

In considering the problem of furnishing telephone service to large buildings, it is quite impracticable and uneconomical to place a pair of wires through the building each time a telephone is required. Buildings of these types are generally given service by means of house cable which is placed in the building during its construction, and provides facilities which will permit convenient and efficient connections of telephones at any location within the building. The house cable system is usually designed to meet the maximum requirements of the building with sufficient flexibility to care for any changes in the relocation of the telephones or for any rearrangements to the building.

These systems usually consist of one or more riser cables starting directly from an entrance cable or from a main cross-connecting terminal or frame in the basement, and extending up through shafts or conduits of the building. Branch cables on each floor are terminated at suitable distribution points by means of floor terminals, where connections are made to the subscriber's telephones by wires.

The general arrangement of the house cable system is almost identical to the general outside plant arrangement in a central office area in that the riser cables may be likened to the main underground cable, the floor branch cables to the subsidiary distribution cables and the floors themselves to individual blocks or areas along a feeder route.

## Class of Buildings

For the purposes of house cable design, large buildings are put into one of 2 classifications, depending upon the expected permanency of stations, both as to number and location, as follows:

1. *Office and loft buildings* in which telephones do not remain fixed either in number or location for any extended period but vary with the requirements of the individual, who will use more or less telephone service according to respective activities.
2. *Hotel and apartment houses* in which the number and location of telephones are fairly definitely fixed by the number and arrangement of rooms or apartments in the building and the telephone service required by successive occupants is approximately the same.

## Planning for Requirements

Unless suitable housing facilities are provided in advance for accommodating cables and wires and for passing them through the walls and floors, either exposed telephone installations will result in unsightly conditions, subject to possible damage with subsequent undesirable effects on service, or extensive costly alterations may be required after completion of the building to conceal effectively all cables and wires. These systems of housing facilities include cable and wireshafts, conduit boxes, molding raceways, underfloor ducts, etc., and are designed to conform to the maximum requirements in common with the water, gas, electric light, and power conduits as an integral part of the building. The vertical accommodations (for the riser cables) start from the basement and rise to the top floor connecting at the various floors with horizontal housing facilities, and junctions between cable conduits are effected by means of splicing closets or splicing and terminal boxes whereby complete passage is afforded for cable and wire from the basement to the location of the station.

Consideration is given to the intended present and future use of a building, the character of its location and average rental value in order to design the cable plant to meet the conditions. Experience has shown that maximum circuit requirements have a definite relation to rentable or productive floor area and this relation is the basis for both house cable and housing system design. Pair density factors expressing the relation between rentable or usable floor area and cable pairs provided have been developed for certain cities by an analysis of the use being made of house cable in existing buildings. From these data broad averages have been derived in the form of ranges of

---

Full text of a portion of "Use of Cables for Telephone Distribution Purposes" (No. 32-121) presented at the A.I.E.E. Middle Eastern District meeting, Baltimore, Md., Oct. 10-13, 1932.

the number of riser cable pairs per unit of floor area which would provide liberal facilities for the developments realized. These factors are used in determining the amount of facilities to be provided in any particular new problem by applying them to the rentable or usable floor areas.

## CABLE ENTRANCE AND MAIN CROSS-CONNECTING TERMINALS

The cable entrance point is selected with the object of establishing the shortest satisfactory route from the point of connection with the feeder system. Cables are preferably attached to walls or ceilings rather than to partitions which are subject to removal or changes. The number of entrance cable pairs to buildings not served largely by one or several local switchboards is determined in the same manner as the facilities to be provided within the building. The number of entrance cable pairs in a building having private branch exchange service is designed to meet the requirements of one or several switchboards; that is, provide trunk lines, telephone power lines, and facilities for outside extensions, if any, including a surplus of pairs to insure adequacy and also provide central office feeders for stations other than extensions on the switchboard. In some cases the building entrance cable includes facilities for extensions to the adjacent block plant.

The main cross-connecting terminal or frame, shown in Fig. 1, is usually in the basement at or near the foot of the riser shaft or conduit. The specific location should be determined upon in advance of the building construction in order that the required space may be set aside and the necessary housing accommodations be installed as the building is erected.

## RISER CABLES AND HOUSINGS

Riser cables, Fig. 2, are designed as nearly as practicable to intersect the floors at the wire centers as determined by study of the typical floor plans. Specific location for the riser cable housing is preferably a permanent corridor partition or in the wall of some public place leading from the corridor and easily accessible without annoyance to the tenants of the building.

In buildings having large distribution areas or in which each floor is made up of several distinct distribution areas, 2 or more riser systems may be desirable, each being used to serve a definite floor area centering about it. In office buildings containing several riser systems, these systems are tied together at certain floors with conduit of sufficient size to house a cable containing enough pairs to permit concentrating the entire floor system on any one riser.

Floor cable and wire housings in combination, afford passage for the telephone circuits from the riser system to the approximate locations of the individual telephones. Cable housings extend more or less directly from the riser to wiring centers on the floor where floor distribution terminals are located and where connection is made with the housings for wire. The floor cable housing system must accommodate a floor distribution cable plant which provides adequate facilities to meet the demand for telephone service on the floor wherever and in whatever quantity it may be. The first step in the design of the system is the determination of the number of cables, including terminals which it will house, their location and size. In small buildings, where the amount of floor distribution is not extensive, the housing system may carry cables and wires together in such raceways as hollow moldings or baseboards. In most

Fig. 2. (Middle) Section of house cable system in loft of large office building, showing type of riser cable shaft and riser cables
Fig. 3. (Right) Section of house cable run in loft of large building

buildings, however, separate systems for cable and wire are necessary, although it is usually quite practical and economical to place small cables in lieu of wire in housings intended for wire when special distribution requirements make this desirable.

# Centrifugal Air Cleaners Serve Railway Equipment

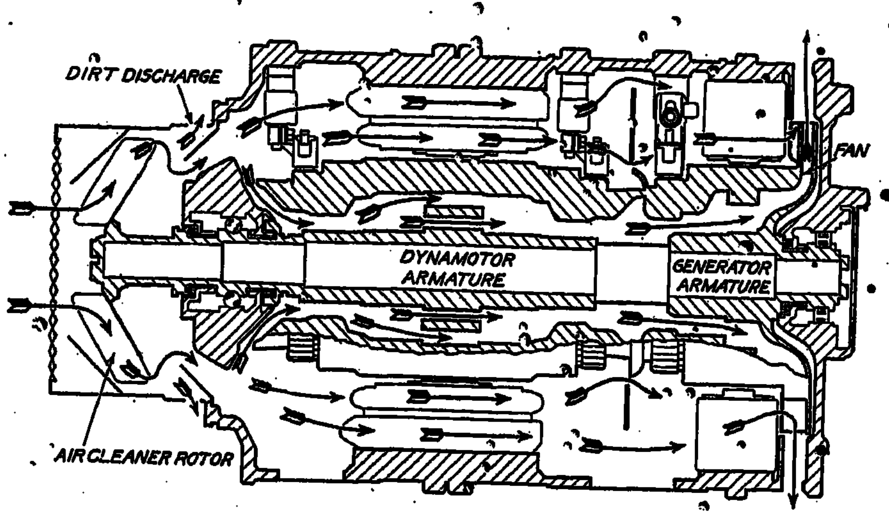
**Here is given a description of a railway dynamotor-control generator set designed for compactness and fitted with centrifugal air cleaning device, as used on cars for the Lackawanna electrification.**

By
M. J. BALDWIN
ASSOCIATE A.I.E.E.

General Elec. Co.,
Erie, Pa.

THE DESIGN, and particularly the ventilation of the dynamotor-control generator sets used on the 3,000-volt d-c motor cars in service on Delaware, Lackawanna & Western Railroad, involve several features which are somewhat unusual for electric motor car equipment. This set provides a 1,500-volt source of power for the compressor and 40 volts for lights, control, and storage battery charging.

To avoid encroaching upon available passenger space, the set was mounted feet up under the car body between the trucks where the ventilating air available is likely to be dirty. Because of the long ducts that would have been required, it was considered impractical to obtain an air supply through the settling chambers provided over the vestibules to supply air for the traction motors (J. C. Aydelot, "Motors for 3,000-Volt Multiple Unit Cars," ELECTRICAL ENGINEERING, June 1932, p. 401). The alternative of totally enclosing the set also was discussed, but the machine could be made so much smaller and lighter if well ventilated that the idea was rejected. Since centrifugal air cleaning devices to furnish about the same volume of air already were in use in other classes of service, a test machine was constructed with such a device and tests were made to determine the cleaning efficiency. On test the cleaner performed creditably, removing from the air practically all the denser materials such as iron filings and a large percentage of the lighter materials such as powdered talc. These materials were selected for the test as being comparable to brake shoe dust and fine snow, the two most detrimental materials normally encountered. For approximately 2 years these machines have been in service on 141 motor cars, without any trouble chargeable to foreign matter in the ventilating air.



A self-ventilating duplex railway machine

General design of the entire set is shown in the accompanying sectional view, where it may be seen that the radial blades of the centrifugal cleaner impart a swirling motion to the entering air which causes all particles heavier than the air to be thrown to the outer casing of the cleaner. As the air is drawn toward the machine by the exhaust fan a conical splitter divides air stream; the air near the surface of the casing and carrying most of the dirt being ejected, and the air remaining at the center entering the machine. The clean air then is divided further: one stream passes over the commutator, around the brush holders, through the air gap and the spaces between the field coils, and out through the fan and exhaust openings; the other stream passes beneath the commutator, through the longitudinal ducts in the armature cores, and out through the fan and exhaust ports.

Although the control generator is a low voltage machine and hence not readily rendered inoperative by dirt, a supply of clean air for it, too, is highly desirable in order to reduce both brush and commutator wear by excluding most of the abrasive matter from the cooling air. To enable one cleaner and one fan to serve the set, the motor and the generator are ventilated in series, with the generator in second position principally because it is the smaller machine and because the low voltage permitted more flexibility in design. However, since the volume of air used is so great that the temperature rise of the air in passing through the dynamotor is only about 14 deg C, the increase in generator size due to the prewarming of the air is unimportant and is believed entirely justified by the lower generator maintenance.

Mounting the generator within the dynamotor frame, while done primarily to obtain clean air, presents several other advantages:

1. To reduce the over-all length of the set to a minimum, and thereby permit a short, stiff shaft to be used, the control generator was made abnormally large in diameter and short. As a separate machine of this diameter the weight and space of the generator would not be economical, but as an addition to machine of inherently large diameter, the weight and space requirements actually are less than if a smaller diameter had been used.

---

Written especially for ELECTRICAL ENGINEERING. *Not published in pamphlet form.*

2. The problem of obtaining good commutation was simplified by the short length of core which decreases the sparking reactance voltage.

3. The large generator diameter makes possible a large radial air space between the bearing and the end windings permitting the bearing to be recessed under the fan, thus shortening the set.

4. Maintenance cost is less because the control generator need not be removed before disassembling the armature, as probably would have been necessary with an overhung design.

When operating at a 2,700-volt average trolley potential the dynamotor will deliver 4.6 amp from the mid-tap for the operation of the air compressor. Simultaneously from the control generator a maximum continuous output of 4.5 kw at 40 volts is available without exceeding a temperature rise of 85 degrees C by resistance in any winding.

The set is semi-fabricated and weighs 2,630 lb complete with air cleaner. Provision is made for convenient inspection of commutator and brushes through openings in the frame normally covered by flexible strap girdles. To insure against the high voltage of the dynamotor being imposed upon the low voltage circuits of the control generator, should an arc to ground or a flashover of the low voltage dynamotor commutator ever occur, a steel flash barrier separates the two commutators which are adjacent and in the center of the set.

# Locating Faults in Power Cables

Power cable fault locating is at times difficult due to a high initial fault resistance or an increase of resistance during the time locating is in progress. A method using a constant current transformer for reducing high initial resistance and preventing its increase, in connection with a short circuiting switch to generate signals for locating the fault, is discussed in this article. A practical assembly of this type of apparatus for cable fault locating is described and operating directions are included.

W. P. TAYLOR
ASSOCIATE A.I.E.E.

Consolidated Gas Elec. Lt. and Pwr. Co. of Baltimore, Md.

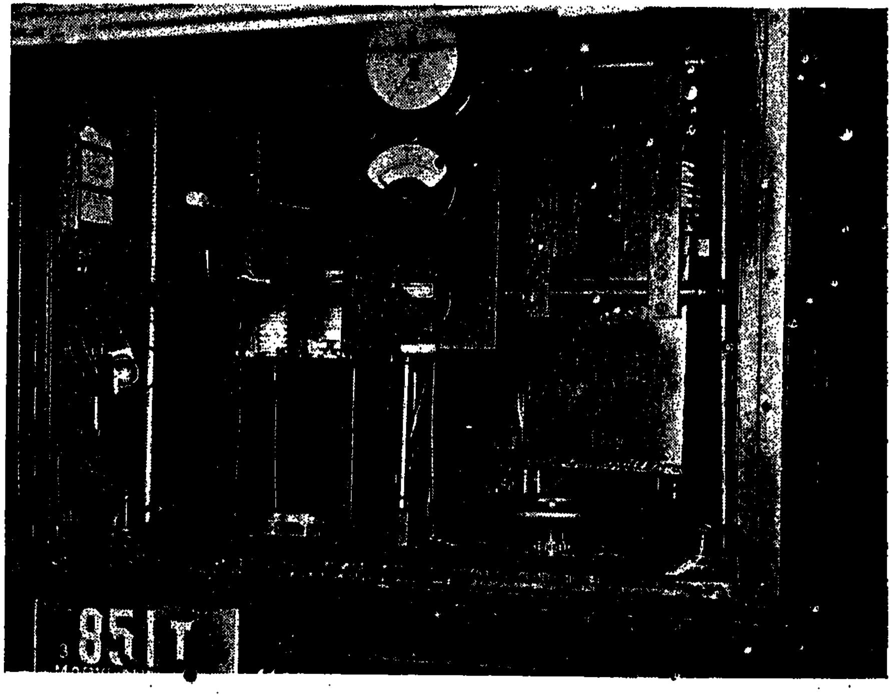

**Fig. 1. Front view of portable cable fault locater mounted on a $1^1/_2$-ton trailer**

A 50-kw 6.6-amp constant current transformer is used to furnish current for carbonizing the fault and signaling. The low voltage rating is 2,300 volts and 25 cycles. The 2 high voltage coils can be connected in series or in parallel; connections are by wingnut and bolt, with a fiber sleeve for insulation over the connection. Coil position is regulated by the hand wheel. Steel spark gaps limit the maximum voltage delivered. The meters on the panel indicate the current and voltage being applied to the cable. A 200-va potential transformer supplies 2 lights and power to drive the rotary shorting switch

THE LOCATION of power cable faults has been facilitated by the design of the portable cable fault locater shown in Figs. 1 and 2, combining a constant current transformer and short circuiting switch with suitable accessory apparatus. Two general methods are in use for locating faults in power cables. One of these involves the use of a bridge to measure the resistance of a conductor to the fault and thus gage its distance from the test station. The other method, and the one on which this portable fault locater is based, requires a signal current to be passed through the conductor to the fault. With this method an exploring coil is held successively at different points along the faulted cable, and an audible indication of the fault location is given by a head-phone connected to the exploring coil.

An investigation started several years ago indicated that the audible signal method was preferable and that some scheme was necessary for reducing the resistance of high resistance faults, and maintaining the fault resistance constant at a low value during the test period. These requirements have been met in the portable fault locater by the use of a constant current transformer for burning and reducing

---

Esentially full text of "Locating Power Cable Faults by Means of a Constant Current Transformer With Short Circuiting Switch" presented at a meeting of the A.I.E.E. Baltimore (Md.) Section, May 15, 1931. This paper was awarded the 1931 A.I.E.E. Middle Eastern District prizes, both for best paper and initial paper.

cable faults as well as the generation of a signal current, obtained by means of a rotary switch which intermittently short circuits the secondary of the constant current transformer. A schematic diagram of the cable fault locater is shown in Fig. 3, and the rotary shorting switch in Fig. 4. The great advantage of this method is that the fault is not lost during the process of locating. A not unusual and extremely exasperating experience in fault locating by some other methods is the frequent loss of faults due to healing when low voltage signal current is used, requiring repetition of high voltage tests.

## Fault Reduction

The previously known advantages of a constant current transformer for burning a cable fault are utilized in this equipment. If a fault exists and the voltage applied is high enough to cause an appreciable current flow, the fault will commence to carbonize and the resistance will be reduced. Where the resistance is high, advantage frequently may be taken of the fact that the capacity of the cable in conjunction with the reactance of the transformer may give a condition approaching resonance, thus increasing the applied voltage in excess of the open circuit voltage of the transformer. The different voltages which are possible are illustrated in Fig. 5. A spark gap connected across the cable eliminates the possibility of dangerous voltages in case there is no cable fault to retard the rise.

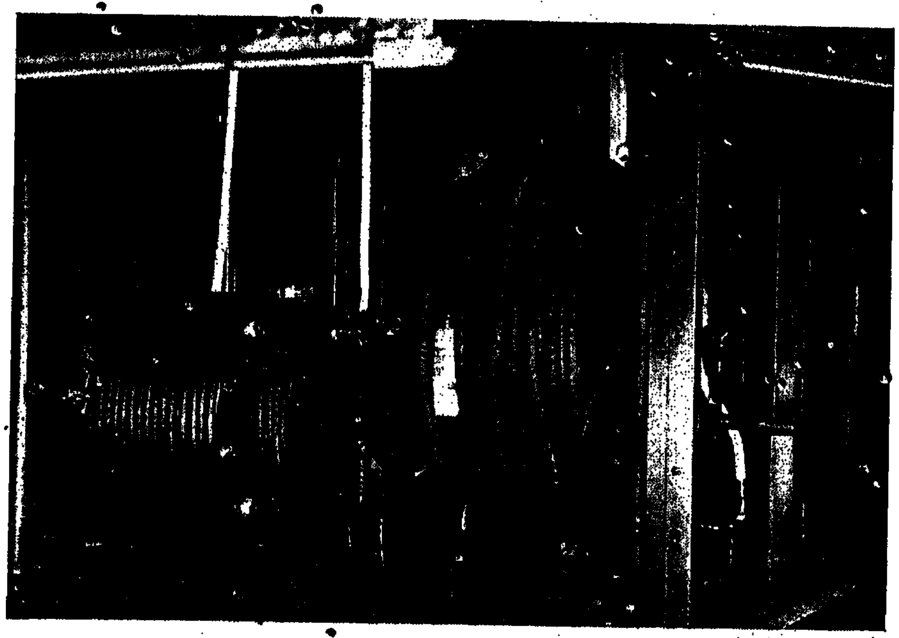

Fig. 2. Rear view of portable cable fault locater

Reels hold lengths of insulated leads for connecting to power supply, ground, and faulty cable. These reels can be locked in position. Removable handles are used when the leads are to be wound up. Suitable clamps are used on the lead ends to facilitate connecting. Connection between the leads on the reels and the wiring on the trailer is made by wingnuts and bolts, with fiber sleeves for insulation

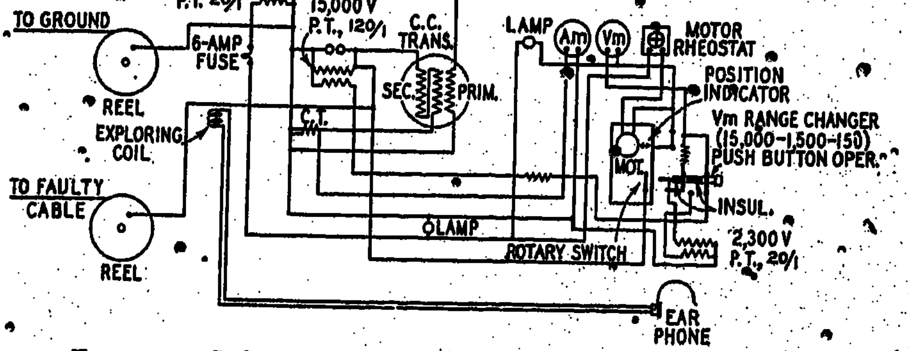

Fig. 3. Schematic diagram of cable fault locater designed primarily for 13,000-volt power cables

The initial voltage available for application to the cable can be varied by changing the amount of connected cable capacity or by changing the inductive reactance of the constant current transformer through a change in coil connection or position. The characteristics of the transformer limit the current to a safe value, and after reducing the resistance of the fault, the current maintains this resistance constant at a low value while the signal current is generated by the rotary shorting switch. The nearly continuous carbonizing effect of the power current is thus obtained simultaneously with the sending of the signal. Tests have proved the method quite satisfactory in regard to signal quality; and in addition a long life of switch contacts is secured due to the absence of high voltage during operation of the shorting switch.

## Operation of Cable Fault Locater

The portable cable fault locater shown in Figs. 1 to 4 is held is readiness in a station where most trouble is expected. Tie cables frequently can be used to connect the locater to faulty cable at other stations. The actual operating procedure for locating a cable fault with this equipment may be outlined as follows:

1. As soon as a fault has occurred, the cable in trouble should be isolated from all apparatus by opening the pothead disconnecting switches. No checking for faulty phase or continuity is necessary.

2. With cutout and oil switch on the locater open, connections are

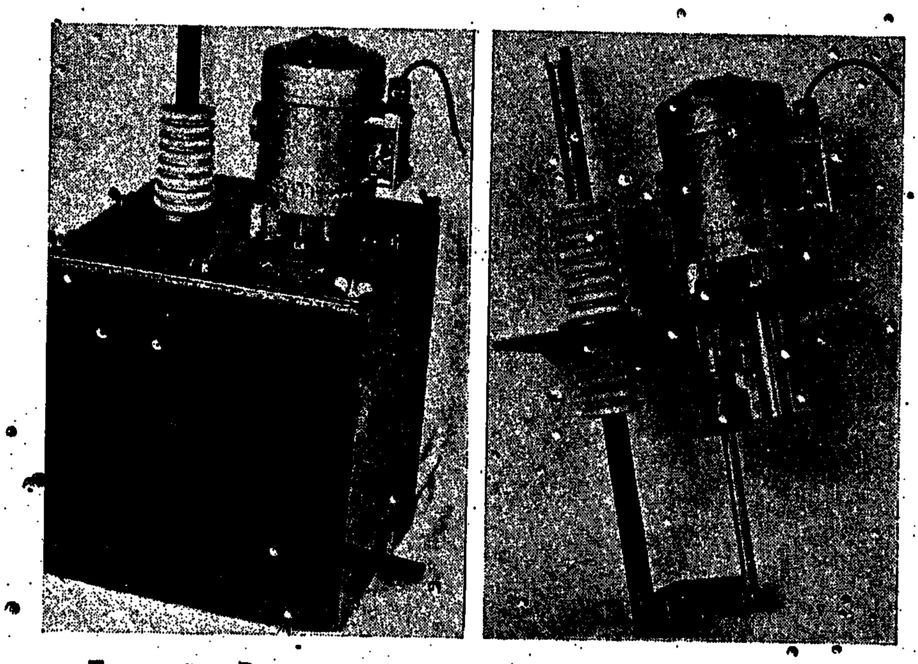

Fig. 4. Rotary switch for intermittently short circuiting the secondary of the constant current transformer in order to utilize the fault reducing current as signal current

An electric drill with a universal motor is used to supply power and reduction gearing. The fixed contact is copper and the moving one is sheet brass or bronze. Oil is used in the tank for insulating and cooling. An indicator needle on the top of the casing and connected by gearing with the moving contact shaft shows the position of the moving contact. A rheostat controls the speed of the motor now made to ground, a 2,300-volt supply (either 25 or 60 cycles) and the 3 conductors of the faulty cable at its pothead disconnecting switches. (If isolated phase system is used, test bus can be used, tying in at the most convenient point.)

3. The 2,300-volt cutout on the locater is now closed. A lamp now lights on the trailer and indicates the supply is alive up to the oil switch. The transformer coils are now set at a maximum distance apart.

4. After first checking that the rotary switch is open, the locater oil switch is closed, and the voltmeter is read. If the voltage wavers, current is being passed through the fault and it is allowed to burn for a while. If the voltage drops rapidly, the carbonizing is satisfactory. If the dropping in voltage takes place slowly it can sometimes be speeded by paralleling the secondary coils or moving the transformer coils closer together. In any event the burning process must continue until the voltage is quite low. For best results it should be 100 volts or lower with the current at 6.6 amp before the signal is put on.

5. In case the voltage does not vary after the cable is made alive, no burning action is taking place. If the voltage shows below the open circuit voltage of the constant current transformer, the connected cable has too great a capacity. To reduce it, reduce the number of phases tied to the locater, tying the extra ones to ground. Now apply voltage again with the locater. If a voltage above open circuit is reached with no evidence of the fault burning, it is probable that the faulty phase is tied to ground. Switch phases and try again.

6. After the fault has properly carbonized, indicated by the voltage being steady and below 100 volts at 6.6 amp, the signal is put on the cable by running the rotary shorting switch. Listening to the phone the speed of the shorting switch is adjusted, by means of the rheostat, to give a ticking sound at about 200 cycles per min.

7. The exploring coil and phone shown in Fig. 6 are carried to cable manholes. Hearing the signal in one hole and getting no signal at the next hole away from the sending station, indicates the fault is between the 2 holes. Care should be taken to place the exploring coil on the cable beyond the cable bonds on the side away from the sending station.

A record of voltages and currents, time to carbonize and locate, should be kept together with notes on the fault. After a little experience with the action of the locater on various type faults, some prediction can be made as to the type fault and whether located in a wet or dry place.

## ACTUAL CABLE FAULTS LOCATED

During a period of $1^1/_2$ years previous to the design of the locater described, 26 power cable faults on the system of the Consolidated Gas Electric Light and Power Company of Baltimore were located successfully by the use of constant current transformer equipment, using 15-kw, 30-kw, or 50-kw transformers. During this period there was only one failure to locate the fault, and this was caused by a personal error and was not due to any defect in the method.

Records have been kept for all faults located (mostly on 13,000-volt cable) and these show that although some stubborn cases required over 2 hr from the time voltage was applied until the fault was located, the great majority required less than one hr. In almost all cases, the fault resistance was reduced sufficiently in a very few minutes so that the test signal could be applied. Voltage readings were taken during each test and these show that on 13,000-volt paper insulated lead sheath cable, some faults may require an initial voltage of 15,000 volts or higher in order to start carbonization of the fault. As the open circuit voltage of a 50-kw 6.6-amp constant current transformer is only about 8,000 volts, the value of the resonance relation for boosting this voltage is quite evident. The maximum voltages measured covered the range from over 15,000 volts down to almost zero, indicating a wide range of fault resistances.

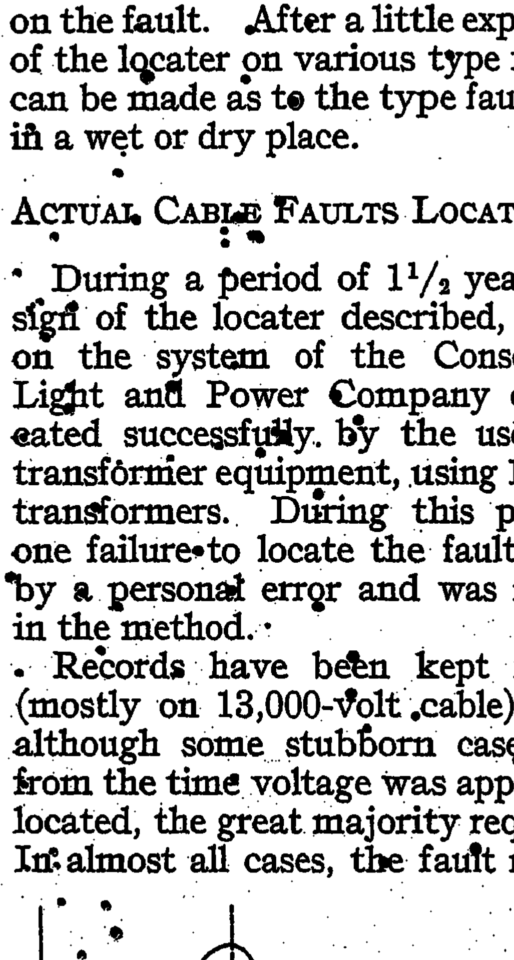

**Fig. 5. General shape of curve of voltage applied by a constant current transformer to a cable without fault**

In quite a number of cases smoke could be seen leaving the duct or could be smelled at the manhole near the fault, thus indicating the close presence of the burning fault. As the current is limited to 6.6 amp there is no damage to nearby cables and yet the current is sufficient to cause a small amount of smoke in most instances, thus assisting in locating the fault.

Two faults in 4,000-volt cables were located and these generally required the application of less voltage. Three faults in 26,000-volt cables were located, 2 of these being in submarine cables. The latter cables, being submerged in water, are particularly difficult to handle, although the appearance of bubbles in the water over the fault may assist in the fault location. A large exploring coil with simple 2-stage amplifier and head-phones carried in a row boat, have been used to locate faults in submarine cable, although some difficulty in distinguishing the signal was encountered over deep water (35 ft) due to the number of foreign sounds picked up. In this case, however, the vicinity of fault was located, and the cable was pulled up by a grappling hook quite close to the actual fault.

Although constant current transformers have been used previously for reducing cable fault resistance, the use of the constant current transformer both for reducing the fault resistance and for sending a signal to locate the fault is believed to be original. That these ideas are practical has been proved by the record of successful operation on a large number of power cable faults.

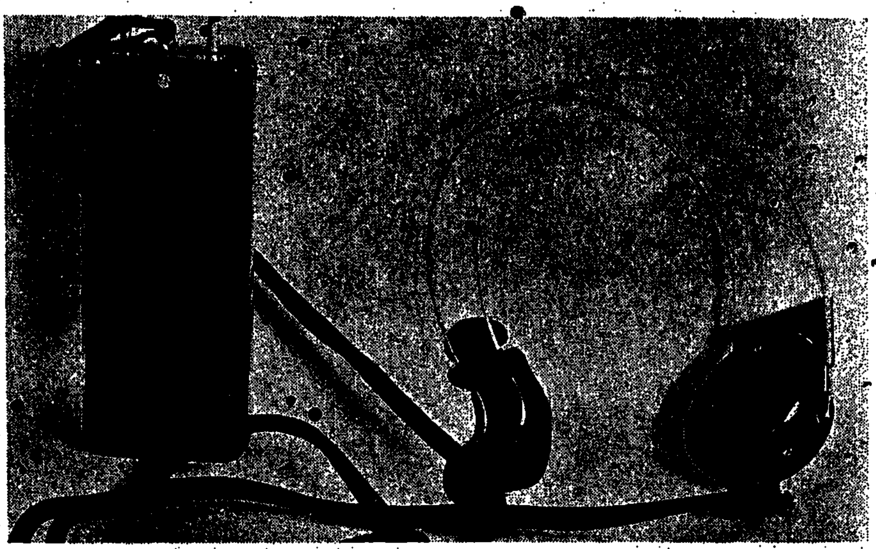

**Fig. 6. Small exploring coil and head-phone normally used to locate the manholes between which the fault is located**

A larger coil and amplifier are used in special cases where it is impossible to put the coil directly on the cable sheath

# Winter Convention Technical Program Announced

PLANS for the technical program as tentatively arranged for the coming winter convention of the Institute to be held in the Engineering Societies Building, 33 West 39th Street, New York, N. Y., January 23–27, 1933, will convince most electrical engineers that more than the usual number of papers which are of wide interest will be presented. The technical program committee has used great care in the selection of papers which deal with problems most important to the electrical industry at the present time.

Inspection trips, presentation of the Edison Medal, and entertainment features for both men and women are being arranged by the various subcommittees and will be announced in the January 1933 issue of Electrical Engineering. The chairmen of these subcommittees are: convention executive committee, C. R. Jones, Westinghouse Electric & Mfg. Co., New York, N. Y.; dinner-dance committee, C. R. Beardsley, Brooklyn Edison Co., Brooklyn, N. Y.; smoker committee, R. A. McClenahen, United Engineers & Constructors, Inc., Newark, N. J.; inspection trips committee, W. R. Smith, United Engineers & Constructors, Inc., Newark, N. J.; and the ladies' committee, Mrs. E. B. Meyer, South Orange, N. J.

### Technical Sessions

Notwithstanding adverse business conditions the Institute offers its membership an unusual opportunity to hear and take part in the discussion of the most recent advances that have been made in a number of specialized fields of the electrical industry. Thirteen sessions in all have been scheduled during the 5 days of the convention. These sessions have been paralleled so that those which hold interests in common conflict the least with one another and yet related subjects have been grouped close together to permit members who cannot stay for the entire week of the convention to obtain the most that is of interest to them in a shorter interval of time.

Each of several timely sessions have evolved from the close cooperation and united efforts of more than one committee. The communication requirements of railroads will be presented by authors representing 5 well known carriers. This session is under the auspices of the committee on communication, assisted by transportation subcommittee; it should prove to be of particular interest to engineers in both the communication and transportation fields. In addition, there will be another session dealing entirely with transportation problems. One of the papers in this session will present valuable operating data on the Cleveland Union Terminal electrification. One of the electrical machinery sessions, the lightning session, and several papers in the instruments and measurements sessions are closely related. The first treats the problem of insulation coordination, the second deals with lightning and impulse voltage experience with insulators and wood construction, and the third presents the measurement of impulse voltages. The papers which in all probability will be presented in the above sessions, as well as the various other sessions, are listed herewith.

## Tentative Technical Program

### Monday, January 23

**10:00 a.m.—Registration**

**2:00 p.m.—Opening of Convention**

**—(A) Automatic Stations**

Pipe Line Pumping and Automatic Control, John Fies, Texas Power and Light Co.

*The Principle of Condenser Discharge Applied to Central Station Control Problems, F. H. Gulliksen, Westinghouse Electric & Mfg. Co.

*Principles of the Direct-Selection System of Supervisory Control, M. E. Reagan, Westinghouse Electric & Mfg. Co.

*Operating Experience With Automatic and Supervisory Control, J. A. Noertker, The Cincinnati Street Railway Co.

**2:00 p.m.—(B) Electric Welding**

*†Preliminary Report of Research Work Dealing With Nottingham's Equations and the Boiling Points of Anodes in Relation to the Anode Drop in Potential, J. L. Myer, Lehigh University.

*A Natural Arc Welding Generator, G. A. Johnstone, Great Lakes Electric Mfg. Co., Chicago, Ill.

*Transients in Arc Welding Generators, A. R. Miller, Lehigh University.

*High Velocity Vapor Stream in the Vacuum Arc, R. C. Mason, Westinghouse Electric & Mfg. Co.

*Performance and Design of Electric Welders With Controlled Transients, F. Creedy, Lehigh University.

### Tuesday, January 24

**10:00 a.m.—(C) Communication**

Communication Requirements of Railroads, J. L. Niesse, New York Central Railroad Co., and R. C. Thayer, Great Northern Railway Co.

Communication System on the Pennsylvania Railroad, I. C. Forshee, Pennsylvania Railroad.

Railroad Signaling and Train Control, R. B. Amsden and W. M. Vandersluis, Illinois Central Railroad.

Modern Signaling on the Reading Railroad, E. W. Reich and G. I. Wright, Reading Co.

Centralized Traffic Control and Train Control of the Baltimore and Ohio Railroad, J. H. Davis and G. H. Dryden, Baltimore and Ohio Railroad.

**10:00 a.m.—(D) Rotating Electrical Machinery**

Low-Frequency Self-Exciting Commutator Generator, J. I. Hull, General Electric Co.

Some Factors Affecting Temperature Rise in Armatures of Electrical Machines, C. J. Fechheimer, Consulting Engineer.

Parallel Operation of A-C Generators—Action of Governors and Damper Windings, M. Stone, Westinghouse Electric & Mfg. Co.

Synchronous Motor Pulling-Into-Step Phenomena, H. E. Edgerton, Massachusetts Institute of Technology.

Two-Reaction Theory of Synchronous Machines—Part II, R. H. Park, Calco Chemical Co.

**2:00 p.m.—(E) Transportation**

*Application of Air Conditioning to Railroad Passenger Cars, W. C. Goodwin and Charles Kerr, Jr., Westinghouse Electric & Mfg. Co.

*Calculation of Single Phase Series Motor Control Characteristics, H. G. Moore and C. J. Axtell, General Electric Co.

*Operating Data on the Cleveland Union Terminal Electrification, F. H. Craton, General Electric Co.

Power Supply for Main Line Railway Contact Systems, P. A. McGee, Reading Railroad Co., and E. L. Harder, Westinghouse Electric & Mfg. Co.

Simplified Speed Control for Single Phase Locomotives, W. A. Giger, Allis Chalmers Mfg. Co.

### Wednesday, January 25

**10:00 a.m.—(F) Education**

Address—The Professional Development of the Engineer, R. I. Rees, American Telephone & Telegraph Co.

**10:00 a.m.—(G) Insulation Coordination**

*Progress Report on Impulse Testing of Commercial Transformers, F. J. Vogel, Westinghouse Electric & Mfg. Co., and V. M. Montsinger, General Electric Co.

*Factors Influencing the Insulation Coordination of Transformers, F. J. Vogel, Westinghouse Electric & Mfg. Co.

*Coordination of Insulation, V. M. Montsinger, W. L. Lloyd, Jr., and J. E. Clem, General Electric Co.

*Recent Developments in High-Current Mercury-Arc Rectifiers, E. H. Reid and C. C. Herskind, General Electric Co.

*Synchronous-Mechanical Rectifier-Inverter, S. S. Seyfert, Lehigh University.

### Thursday, January 26

**10:00 a.m.—(H) Lightning**

*Impulse Testing Recommendations, Subcommittee on Lightning and Insulators, Philip Sporn, Chairman.

*Lightning Investigation on Transmission Lines—III, W. W. Lewis and C. M. Foust, General Electric Co.

*Lightning Experience on 132-Kv Lines of the American Gas and Electric Company System, Philip Sporn, American Gas and Electric Co.

*Impulse and Dynamic Flashover Studies of 26-Kv Wood Pole Transmission Construction, A. S. Brookes and R. N. Southgate, Public Service Electric & Gas Co., and E. R. Whitehead, Westinghouse Electric & Mfg. Co.

*Operating Experience With Wood Utilized As Lightning Insulation, H. L. Melvin, Electric Bond and Share Co.

10:00 a.m.—(I) Electrochemistry and Electrometallurgy

Address—Increasing Applications of Electricity to Chemical Processes, Colin G. Fink, Columbia University.

*Light Sensitive Industrial Process Control, J. V. Alfriend, Jr., Westinghouse Electric & Mfg. Co.

2:00 p.m.—(J) Instruments and Measurements

A Standard of Low Power Factor, W. B. Kouwenhoven and L. J. Berberich, The Johns Hopkins University.

A Bridge for Precision Power Factor Measurements on Small Oil Samples, J. C. Balsbaugh and P. H. Moon, Massachusetts Institute of Technology.

Skin Effect in Rectangular Conductors—A Method of Measurement and Experimental Data, H. C. Forbes and L. J. Gorman, The New York Edison Co.

*Impulse Voltage Testing, C. F. Harding and C. S. Sprague, Purdue University.

*The Measurement of High Surge Voltages, P. L. Bellaschi, Westinghouse Electric and Mfg. Co.

*Laboratory Measurement of Impulse Voltages, J. C. Dowell and C. M. Foust, General Electric Co.

2:00 p.m.—(K) Industrial Applications

*Circuit Breaker Protection for Industrial Circuits, H. J. Lingal and O. S. Jennings, Westinghouse Electric & Mfg. Co.

*Variable Voltage Equipment for Oil Well Drilling, A. H. Albrecht, Standard Oil Co. of Calif.

*Recent Developments in Electronic Devices for Industrial Control, F. H. Gulliksen, Westinghouse Electric & Mfg. Co.

**Friday, January 27**

10:00 a.m.—(L) Protective Devices

The Use of Communication Facilities in Transmission Line Relaying, J. H. Neher, Philadelphia Electric Co.

Protection of Electrical Apparatus—Recommended Practise, Relay Subcommittee, O. C. Traver, Chairman.

A Sequence Relay for Network Protectors, H. S. Orcutt, United Electric Light and Power Co., and M. A. Bostwick, Westinghouse Electric & Mfg. Co.

Phase Sequence Relaying, H. R. Searing, The New York Edison Company and The United Electric Light & Power Co., and R. E. Powers, Westinghouse Electric & Mfg. Co.

10:00 a.m.—(M) Selected Subjects

Higher Steam Pressures and Temperatures—A Challenge to Engineers, M. D. Engle and I. E. Moultrop, The Edison Electric Illuminating Co. of Boston.

*Actions Taken by the Symbols, Units, and Nomenclature Committee of the International Union of Pure and Applied Physics, A. E. Kennelly, Harvard University.

Empirical Equations for the Magnetization Curve, J. P. Barton, Milwaukee, Wis.

†Tensor Analysis of Rotating Machinery, Gabriel Kron, United Research Corp.

2:00 p.m.—(N) Research and Applied Electronics

The Dielectric Losses in Impregnated Paper, J. B. Whitehead, The Johns Hopkins University.

Applications of Harmonic Commutation for Thyratron Converters, C. H. Willis, Princeton University.

*Ignition of Arcs in Vapor Discharge Tubes, J. Slepian and L. R. Ludwig, Westinghouse Electric & Mfg. Co.

*Capacitance and Loss Variations With Frequency and Temperature in Composite Insulation, H. H. Race, General Electric Co.

---

* These papers are under consideration for presentation at the winter convention, but up to date of going to press have not been officially placed upon the program.

† These papers will not be published in advance form by the Institute but copies may be made available by the respective authors.

### Rules on Presenting and Discussing Papers

At the technical sessions papers will be presented in abstract, 10 min being allowed for each paper unless otherwise arranged, or the presiding officer meets with the authors preceding the session to arrange the order of presentation and allotment of time for papers and discussion.

Any member is free to discuss any paper when the meeting is thrown open for general discussion. Usually 5 min are allowed each discusser. When a member signifies a desire to discuss papers on other subjects or groups, he shall be permitted a 5-min period for each subject or group.

It is preferable that a member who wishes to discuss a paper give his name beforehand to the presiding officer of the session at which the paper is to be presented. Copies of discussion prepared in advance should be left with the presiding officer. Each discusser is to step to the front of the room and announce, so that all may hear, his name and professional affiliations. Discussions at the technical sessions are not reported. To be considered for publication, discussions should be written and mailed to the A.I.E.E., Editorial Department, 33 West 39th Street, New York, N. Y., on or before Feb. 10, 1933.

**Electric Railway Association Changes Name.**—At the Annual Business Meeting of the American Electric Railway Association held in Chicago, Illinois, the last week in September 1932, the name of this association was changed to the American Transit Association. It is felt that the new name more accurately indicates the scope of the association's functions and activities and its interest in the transportation business. The change in name has been under consideration for several years. To be consistent with the name of the parent association, the names of the 4 affiliated associations were also changed at that time and are now the American Transit Accountants' Association, American Transit Claims Association, American Transit Engineering Association and American Transit Operating Association.

## Utah Section Offers Prizes for Papers

Prizes amounting to $25 have been offered by the Utah Section for papers presented before that Section by its members, according to announcement at the Section's October 10, 1932, meeting in Salt Lake City, by Dr. J. H. Hamilton, chairman of the Section's program committee. Excerpts from the announcement follow:

"To encourage members of the Utah A.I.E.E. Section to present papers before the local Section the executive committee has voted $25 for prize awards. . . . . first prize $15, second prize $10. Papers are to be judged by 3 judges appointed by the executive committee, and prizes will be awarded at the final meeting of the Section. To facilitate the management, the following rules have been established:

1. "The contest is open to an Institute member of any grade and to any person whose application for membership is in process. Application for admission to the contest is to be made to the Section secretary before November 15, 1932, . . . . . [stating] a tentative title of the paper, the approximate length, and the choice as to date of delivery."

2. "The valuation governing the grading of the Section papers in determining the prize award will be identical with those used by the national committee in determining the award of national prizes."

## Student Conference Held by South West District

A Student conference of the Institute's South West District, No. 7, was held October 21 and 22, 1932, at the University of Oklahoma, Norman. In addition to the 4 members of the faculty and 50 junior and senior students from the University of Oklahoma, there were present 106 from other colleges and the Oklahoma City Section. Attendance of the chairmen and counselors, as shown in Table I, was exceptionally good. The absence of the 3 counselors who were not present was unavoidable.

Two meetings of the Branch counselors and Student chairmen were held. Considerable discussion was centered on the present practise in this District of awarding prizes for student papers other than the Institute's usual national and District prizes for Branch papers. It was felt that an element of unfairness resulted from the fact that some of the colleges in the District required undergraduate research and theses, whereas others had no such requirements. In order to obviate this difficulty a motion was passed to the effect that although technical sessions would be held at future meetings, papers by students of the various Branches would not be put in competition, ranked, or prizes offered for the best paper. Other problems discussed at these meetings included means for increasing attendance, improving interest and making the Student Branch more as an introduction to membership in the Institute after graduation.

Three technical sessions were held, at which 10 Student papers were presented. The paper entitled, "The Development of a Medium Priced High Quality Microphone," by J. D. Martin, Jr., of the Missouri School of Mines and Metallurgy, was decided to be the best paper presented at this session, and his Branch was awarded the bronze plaque offered this year by the Oklahoma City Section. The other Student papers presented were as follows:

Construction of WNAD, by Wilmer Ragsdale and Bryan Cole, Okla. Univ.

Recent Developments in the Metering of Electrical Energy, by M. P. Jones, Southern Methodist Univ.

Transmitters for Broadcast Service, by R. D. Compton, Kansas State Col.

Some Fundamentals of Inductive Coordination, by David Sussin, Texas Univ.

Influence of Voltage Variations on Induction Motor Characteristics, by L. C. Wasson, Arkansas Univ.

Economics of Rural Line Distribution, by B. E. Lowe, Okla. A. & M. Col.

A Device for Demonstrating Symmetrical Components, by Stanley Fish and Austin True, Univ. of New Mexico.

An Ultra Short Wave Transmitter, by G. C. Hutcheson, Texas A. & M. Col.

Comparison of Strowger Type With Panel Type Automatic Telephone Equipment, by R. C. Jackson and L. D. Weiser, Univ. of Kansas.

Table I—Counselors and Chairmen Present

| College | Branch Counselor | Student Chairman |
|---|---|---|
| University of Arkansas | W. B. Stelzner | L. C. Wasson |
| Kansas State College | R. G. Kloeffler | G. D. Ferguson (v-chm.) |
| University of Kansas | D. C. Jackson, Jr. | R. C. Jackson |
| Missouri School of Mines | I. H. Lovett | J. D. Martin |
| University of Missouri | M. P. Weinbach | A. L. Coffman |
| University of New Mexico | | Stanley Fish |
| Oklahoma A. & M. College | A. Naeter | J. R. Hollis |
| University of Oklahoma | F. G. Tappan | H. H. Moody |
| Rice Institute | J. S. Waters | E. F. Kinzer |
| Southern Methodist University | H. F. Huffman | R. P. Lindsley |
| A. & M. College of Texas | H. C. Dillingham | G. H. Samuels |
| Texas Technological College | | Preston Conner |
| University of Texas | J. A. Correll | F. C. Sperry |
| Washington University | | C. E. Keiser |

# Changes Made in A.I.E.E. Prizes for Technical Papers

Authors who plan to present papers before the Institute during the calendar year 1933, those who have presented papers during 1932, and others who may wish to submit papers for prizes, would do well to bear in mind that such papers are eligible for consideration for Institute prizes. These awards are made each spring for the preceding calendar year, and fall into 2 main classes, national and District prizes.

On account of the reduced income of the Institute, the board of directors decided to omit the cash awards for papers presented during the calendar year 1932, except that a payment of $25 in cash will accompany each District Prize for Branch Paper. All certificates will be issued as usual, those for national prizes signed by Institute officers, and those for District prizes signed by the officers of the Districts concerned. In cases of joint authorship, a certificate will be issued to each author.

## National Prizes

The national prizes which may be awarded at the discretion of the committee on award of Institute prizes are as follows:

1. Prizes for best papers in (1) *engineering practise,* (2) *theory and research,* and (3) *public relations and education.*
2. Prize for initial paper.
3. Prize for Branch paper.

The national prize for best paper in each of the 3 classes indicated may be awarded to the author or authors of the best original paper presented at any national, District, or Section meeting of the Institute, provided the author, or at least one of coauthors, is a member of the Institute.

The national prize for initial paper may be awarded to the author or authors of the most worthy paper presented at any national, District, Section, or Branch meeting of the Institute, provided the author or authors have never previously presented a paper which has been accepted by the technical program committee, and the author, or at least one of coauthors, is a member of the Institute or is a graduate student enrolled as a Student of the Institute.

The national prize for Branch paper may be awarded to the author or authors of the best paper based upon undergraduate work presented at a Branch or other Student meeting of the Institute, provided the author or authors are Student Branch members.

All papers approved by the technical program committee which are presented at any meeting will be considered by the committee on award for the prizes for best paper and initial paper without being formally offered for competition. All papers other than those presented to the technical program committee must, in order to receive consideration, be submitted in triplicate with a written communication to the national secretary on or before February 15 of the year following the calendar year in which they were presented. This may be done by the author or authors, by an officer of the Institute, or by the executive committees of Sections, or Geographical Districts.

## District Prizes

The following District prizes may be awarded each year in each Geographical District of the Institute.

1. Prize for best paper.
2. Prize for initial paper.
3. Prize for Branch paper.

A District prize may be awarded only to an author who, or to coauthors of whom at least one, is located within the District, and for a paper presented at a meeting held within, or under the auspices of, the District.

The District prize for best paper may be awarded for the best paper presented at a national, District, or Section meeting, provided the author, or at least one of coauthors, is a member of the Institute.

The District prize for initial paper may be awarded for the best paper presented at a national, District, Section, or Branch meeting, provided the author or authors have never before presented a paper before a national, District, or Section meeting of the Institute, and the author, or at least one of coauthors, is a member of the Institute or a Graduate student enrolled as a Student of the Institute.

The District prize for Branch paper may be awarded for the best paper based upon undergraduate work presented at a Branch or other Student meeting of the Institute, the author or authors of which are Student Branch members.

All papers to be considered in competition for District prizes must be submitted in duplicate by the authors or by the officers of the Branch, Section, or District concerned to the District committee on awards on or before January 10 of the year following the calendar year in which the papers have been presented.

Copies of a pamphlet entitled "National and District Prizes" may be secured, without charge, upon application to Institute headquarters.

# Dr. Langmuir Awarded Nobel Prize in Chemistry

The Nobel Prize in chemistry for 1932 has been awarded to Dr. Irving Langmuir, associate director of the research laboratory of the General Electric Company, Schenectady, N. Y. The award will be presented to him in Stockholm, Sweden, on December 10, 1932.

Dr. Langmuir was born in Brooklyn, N. Y., 1881. He graduated from the School of Mines of Columbia University in 1903 and received his master's degree and that of doctor of philosophy from the University of Goettingen, Germany. Honorary degrees have since been awarded him by several institutions. Between 1906 and 1909 he was instructor in chemistry at the

Stevens Institute of Technology, Hoboken, N. J., and since 1909 has been connected with the research laboratory of the General Electric Company.

One of Dr. Langmuir's early achievements was the development of the high intensity incandescent lamp, the bulb of which contained small quantities of either nitrogen or argon. It has been stated that the cost of energy required for electric lighting in this country has been reduced about 50 per cent by this gas filled lamp. Growing out of this work with the incandescent lamp were important discoveries in the field of the vacuum tube. The vast development of radio broadcasting and the use of the vacuum tube in electrical control operations and similar fields can be traced largely to Dr. Langmuir's discoveries. His discovery of the atomic hydrogen method of electric welding also was of great importance, as this permits the welding of metals which formerly could not be joined. His many published papers are considered by scientists to be of considerable value. Dr. Langmuir has been particularly interested in the mechanism of chemical reactions taking place on solid surfaces and is now working out the laws according to which atoms and molecules distribute themselves over surfaces, forming single layers of atoms. These laws are of importance in understanding many simple phenomena, such as those of the spreading of oil films on water and of lubrication.

Dr. Langmuir has received many previous honors. The Nichols Medal was awarded to him by the New York Section of the American Chemical Society, first in 1915 for his work on chemical reactions at low pressures, and again in 1924 for his work on atomic structure. In 1918 he received the Hughes Medal from the Royal Society of London in recognition of his researches in molecular physics. The Rumford Medal was awarded him in 1920 by the American Academy of Arts and Sciences for the thermionic researches and his gas filled incandescent lamp. The Royal Academy of Lincei, Rome, Italy, presented its Cannizaro Prize to him in 1925; he received the Perkins Medal in 1928 and the Chandler Medal in 1930. Earlier this year *Popular Science Monthly* awarded him its annual medal and honorarium of $10,000. Dr. Langmuir is a past-president of the American Chemical Society and is a member of many scientific organizations.

## So. Calif. Edison Names New Executives

According to news dispatches under date of October 19, the board of directors of the Southern California Edison Company, Ltd., Los Angeles, has named G. C. Ward (M'24) as its president and H. J. Bauer as chairman of the Board.

These new officers will fill vacancies caused by the death in April 1932 of the company's former board chairman, J. B. Miller, and in August of its former president, R. H. Ballard. Mr. Bauer has been an Edison director for some time; Mr. Ward has been a company official for many years.

### Data Concerning Appropriations for the 60 Local Sections of the Institute for the Appropriation Year Ending September 30, 1932

| | Section Membership as of Aug. 1, 1931 | Section Appropriations as of Aug. 1, 1931, as Provided by the Bylaws | Net Amounts Paid to Sections in Accordance With Agreements | Net Savings From Normal Appropriations | Percentages of Normal Appropriations Saved |
|---|---|---|---|---|---|
| 1. Sections that did not indicate acceptance of 10% deduction, but which nevertheless show expenditures of less than the annual appropriation | | | | | |
| Connecticut | 263 | $ 438.00 | $ 264.77 | $ 173.23 | 39.5 |
| Iowa | 62 | 237.00 | 98.49 | 138.51 | 58.4 |
| Lehigh Valley | 271 | 446.00 | 420.37 | 25.63 | 5.0 |
| Nebraska | 55 | 230.00 | 59.72 | 170.28 | 74.0 |
| New York | 3,794 | 4,215.67 | 4,011.23 | 204.44 | 4.8 |
| Urbana | 36 | 211.00 | 50.76 | 160.24 | 76.0 |
| Worcester | 61 | 236.00 | 141.00 | 95.00 | 40.0 |
| 2. Sections that have accepted 10% deduction of normal appropriation but have not yet rendered final report of expenditures for year ending September 30, 1932 (thus indicating a possible additional saving) | | | | | |
| Houston | 71 | 246.00 | *221.40 | *24.60 | *10.0 |
| Lynn | 134 | 309.00 | *278.10 | *30.90 | *10.0 |
| Madison | 55 | 230.00 | *207.00 | *23.00 | *10.0 |
| Seattle | 218 | 393.00 | *353.70 | *39.30 | *10.0 |
| 3. Sections that did not accept 10% deduction and expended full appropriation | | | | | |
| Mexico | 94 | 269.00 | 269.00 | 0.0 | 0.0 |
| Milwaukee | 221 | 396.00 | 396.00 | 0.0 | 0.0 |
| Providence | 80 | 255.00 | 255.00 | 0.0 | 0.0 |
| Rochester | 103 | 278.00 | 278.00 | 0.0 | 0.0 |
| 4. Sections that did accept a deduction of 10% or more from normal appropriation | | | | | |
| Akron | 75 | 250.00 | 225.00 | 25.00 | 10.0 |
| Atlanta | 102 | 277.00 | 249.30 | 27.70 | 10.0 |
| Baltimore | 217 | 392.00 | 352.80 | 39.20 | 10.0 |
| Boston | 513 | 688.00 | 619.20 | 68.80 | 10.0 |
| Chicago | 1,098 | 1,273.00 | 1,145.70 | 127.30 | 10.0 |
| Cincinnati | 168 | 343.00 | 308.70 | 34.30 | 10.0 |
| Cleveland | 274 | 449.00 | 404.10 | 44.90 | 10.0 |
| Columbus | 62 | 237.00 | 213.30 | 23.70 | 10.0 |
| Dallas | 114 | 289.00 | 260.10 | 28.90 | 10.0 |
| Denver | 154 | 329.00 | 296.10 | 32.90 | 10.0 |
| Detroit-Ann Arbor | 310 | 485.00 | 436.50 | 48.50 | 10.0 |
| Erie | 99 | 274.00 | 246.60 | 27.40 | 10.0 |
| Fort Wayne | 80 | 255.00 | 196.70 | 58.30 | 22.8 |
| Florida | 42 | 217.00 | 108.45 | 108.55 | 50.0 |
| Indianapolis-Lafayette | 88 | 263.00 | 236.70 | 26.30 | 10.0 |

* Tentative figures pending receipt of reports from Sections listed in Item 2.

# 55 Sections Have Assisted in Meeting Reduced 1931–32 Budget

BECAUSE of the reduced income of the Institute, the board of directors at its meeting held on October 23, 1931, adopted a budget of proposed expenditures for the year 1931–2 materially lower than normal, and invited the Sections to cooperate with the board by keeping their expenditures at least 10 per cent below the amounts which would have been available under the provisions given in the bylaws. The board of directors requested that a statement be published after the close of the year giving full credit to all Sections for their cooperation and showing the percentage of reduction attained by each. This information is given in the accompanying tabulation.

The splendid cooperation extended by a large majority of the Sections is sincerely appreciated and has been of great assistance in the efforts to reduce Institute expenditures wherever practicable without interfering seriously with any of the activities.

# Summarized Review of Baltimore Meeting Discussions

PRINCIPAL discussions of the Baltimore Meeting papers are summarized herewith. The papers to which these discussions refer were abstracted in ELECTRICAL ENGINEERING for September 1932, p. 659–62. Only discussion submitted in writing in accordance with governing A.I.E.E. rules is summarized. Complete discussion, together with all approved papers, will be published in the TRANSACTIONS.

## POWER CABLES

R. J. Wieseman (Passaic, N. J.) discussed the historical background of submarine cable installation, leading up to the 115 kv Columbia River crossing. He felt that these recent installations of long-length high-voltage cables should be a source of comfort and encouragement to the utilities in solving their future transmission problems. Cable manufacturers have eliminated the cable as the "neck in the bottle" of best design of large, high voltage power transmission system.

*Thermal Transients and Oil Demands.*—F. H. Buller (Schenectady, N. Y.) in his discussion of this subject expressed the belief that all who have occasion to make temperature-transient or oil-demand calculations on cables are indebted to the authors for the simplifications which they have devised to render computations less laborious. The discusser had found charts 1 and 2 of the paper useful in obtaining approximate values of the roots of equation 6. He believed their limitations were in the mechanics of reproduction rather than in the underlying theory. The method of evaluating the coefficient $c_n$ described by the authors was believed to be simple in theory and usually useful in practise, particularly if only 3 terms of the infinite series for temperature and oil demand are required. He suggested a mathematical solution and presented equations for use in cumbersome cases where more than 3 terms are required.

E. A. Church (Boston, Mass.) also discussed this subject. One of the important facts that he emphasized was that the temperature and oil demand equations for load suddenly applied (unit function in Heaviside terminology) are functions of the constants of the cable only. A graphical method was described that facilitated evaluation of the integral and overcomes the practical difficulties encountered in solving for the coefficients and exponents of each term of the series.

Another discussion by R. J. Wieseman expressed appreciation for the completeness of the analysis of this subject and the excellent charts developed to simplify the labor of making calculations of thermal transients or oil demands. Researches have shown internal pressures in solid cable to be much higher than realized. High pressures have been formed at the conductor and sheath without indication of a positive pressure in the middle of the insulation. This has not been fully understood, but Mr. Wieseman believed that a mathematical analysis along the lines of this paper might offer an explanation.

*Traveling Wave Voltages.*—L. V. Bewley (Pittsfield, Mass.) in discussing this paper expressed the belief that, when taken in conjunction with an earlier paper dealing with the experimental work, it formed a comprehensive treatment of the problem. He suggested and illustrated with equations several ways for increasing the generality of the paper.

J. E. Clem (Schenectady, N. Y.) discussed this subject and analyzed the voltages set up in a cable at the end of a transmission line by the impact of a traveling wave. Calculations were made in two ways: one on the basis of lumped capacitance, the other taking into account the distributed constants of a cable. A comparison of these calculations and a comparison with the test results indicated that the need of cable protection can be determined by calculations made on the basis of lumped capacitance. It was recommended that any cable installation less than 4,000 ft in length be checked to determine the possible need of protection. If the cable at the exit end is connected to a transformer, or a very high surge impedance, protection should be applied.

## TELEPHONE CABLES

*Electrical Testing in Wire Plants.*—W. A. Del Mar (Yonkers, N. Y.) in discussing this subject described some of the early methods of testing in electric wire manufacture and advocated the use of high frequency alternating current. He asked the authors why a frequency of a few hundred cycles was used when by the use of higher frequencies shock hazard could be avoided, a spark of greater searching ability obtained, and the necessity of grounding the wire avoided. He regarded the high frequency spark as especially useful in finding "pinholes" or other air openings in the insulation, but not reliable as a test for the dielectric strength of a patch.

Another discusser, R. J. Wieseman (Passaic, N. J.) inquired as to the speed at which the wire travels through the testing outfit, the voltage and time values used in making the water test, and the limiting thickness of insulation that could be adequately tested by the spark method.

*Pulp Insulation.*—W. A. Del Mar (Yonkers, N. Y.) discussed this subject and inquired concerning the flexibility of this insulation when applied in layers as heavy as 50 mils or more. In regard to the authors' suggestion of new applications, he asked if any of these had materialized in the interim since the writing of the paper.

R. J. Wieseman (Passaic, N. J.) asked about the nature of the wood pulp now used, with special reference to the possible use of spruce fiber. He also asked if the method of insulating the conductors and assembling would result in a firmer cable. In regard to the antimony-lead sheaths of telephone cables, he inquired if pure lead had been considered for cases where the cable is drawn into ducts.

L. S. Ford (Kearny, N. J.) explained that pulp insulated wire fitted very well into the unit idea of cable layup. The construction has been standardized for 24-gage as well as 26-gage pulp cable and it is just being applied to 22-gage pulp cable. Pulp has not as yet resulted in a new line of cable, but in a new type of an existing series of Nos. 24 and 26 exchange area cables that are lower in first cost and that compare very well in quality with the ribbon-insulated cables which they displace. He predicted that in the future, advantage will be taken of the considerable range of values in weight and diameter admitted by pulp.

*Use of Cables for Telephone Distribution Purposes.*—J. A. Cadwaller (Pittsburgh, Pa.) discussed this subject and described a buried cable distribution system recently installed in a high class residential development near Pittsburgh. The land company reserved a 10-ft strip along the rear property line for the utilities, provided trenches for the cables and excavations for the splicing boxes. Conduits from the houses to the nearest splicing boxes were provided by the individual property owners. The telephone company furnished and installed tape armored distribution cable, splicing boxes, terminals, and 1- or 2-pair lead covered cable from the splicing boxes to the houses. The entire cost of this distribution system to the telephone company closely approximated the estimated cost of an aerial cable job on jointly occupied poles.

L. F. Cromwell in his discussion in connection with this subject emphasized the importance of careful cable-pair multiplying in the design of the cable plant so as to effect a minimum plant investment and minimum annual charges consistent with good service. The real test, he thought, is not encountered when the installation is first completed, but rather when service has increased to such an extent that the cable had a majority of its pairs in use.

Another discussion by C. L. Garrett gave consideration to factors which may tend to reduce the intelligibility of speech reception such as noise, crosstalk, and distortion. He pointed out that these factors must be considered and allowance made for them in the design of the plant.

### Economic Aspects of Water Power

A. E. Bauhan (Newark, N. J.) stated that the paper on this subject treated the relative economies of water and steam power in a thorough and sound manner. One of the points brought out in this discussion was in connection with the introduction of the time element, which brings with it the uncertainties of future loads and future competitive plant costs. The curves in the paper, plotted on the basis of percentage of capacity installed, may show a hydroelectric cost, after the initial development, materially below the hydroelectric value and one must not draw from them the conclusion that the project is economically justified. The discusser suggested going a step further and plotting hydroelectric costs and hydroelectric value against years.

William McClellan (New York, N. Y.) pointed out some of the merits of the same paper. He recommended the reading of the paper by every young engineer, not only for the immediate subject of the discussion, but also for the method the author used which, he said, gives a comprehensive treatment of a most intricate subject.

R. E. B. Sharp (Philadelphia, Pa.) in his discussion of the paper considered the performance obtained by the dual operation of pumps and turbines. He considered the case of the design of a centrifugal pump provided with short vanes having a large angle between these vanes (at discharge) and the tangential. When operating as a pump the losses due to diffusion, caused by too great an angle between the vanes, and consequently too great a rate of area expansion, would result in relatively low efficiency as a pump. However, the steep vane angle and short passages would tend to give relatively high efficiency as a turbine. He thought that there was no basis for the efficiency of any centrifugal pump necessarily being the same when operating as a pump as when operating as a turbine.

J. E. Stewart (Pittsburgh, Pa.) considered that the paper clearly brought out the modern conception that the main value of the utility hydroelectric plant, where there is not a high minimum stream flow, was its capacity. He felt that, unless the flow at hydroelectric stations was backed by natural storage or relatively low cost artificial storage, energy costs for hydroelectric plants usually could not compete with energy from modern steam stations.

Another discussion by Ireal A. Winter (Birmingham, Ala.) called attention to the value of this paper, particularly the part dealing with hydroelectric regeneration equipment. He believed the time is fast approaching when the conception of a wide use of hydroelectric regeneration will mature into a concrete fact.

### Safe Harbor Project

J. R. Baker (Baltimore, Md.) in his discussion of this subject drew attention to the progress in hydroelectric design that has occurred in recent years. A comparison of this plant with the Holtwood plant designed some 20 years earlier showed a striking economy of building volume in the design of the Safe Harbor plant. By more skillful arrangement the building mass and structure also were applied to better purpose. The great advance in hydraulic design was well illustrated by the fact that the controlled water path through the Safe Harbor plant, not withstanding its smaller dimensions, is twice as long horizontally as that in the Holtwood plant.

F. H. Hollister (Chicago, Ill.) in connection with this subject cited the advantage of flat efficiency curves and the advances made in steam turbine and boiler room efficiencies during the last 10 years. He believed that this has made imperative the improvement of the over-all all-day efficiency of the hydroelectric station or else greatly reduce the investment permissible in a low head hydroelectric plant. He also referred to the wisdom of making provisions for automatic bus protection.

A. H. Hull (Toronto, Canada) discussed several features about the development, in order to bring out at greater length some of the considerations that led to the construction adopted. He was impressed with the thorough manner in which the many design problems had been handled, and with the result of a superstructure of pleasing appearance that permitted a compact arrangement of major equipment.

Another discussion by A. B. Lakey (Philadelphia, Pa.) described the construction of the 82-in. pivoted-segment thrust bearings for the Safe Harbor units. These thrust bearings carry a load up to about 750 tons apiece with a resulting unit pressure of 416 lb per sq in. on the 3,600 sq in. net of babbitted bearing-shoe surface. The novelty of the design consists mainly in the ease of vertical adjustment at any time, and in the minimum disturbance of other parts of the unit incidental to inspecting or changing the bearing surfaces.

C. F. Merriam (Baltimore, Md.) described the Safe Harbor governing system, which in many respects represents a distinct advance in power plant design. Operation of the turbines has been concentrated on a single floor by locating pumps and actuators on the same level, with a resultant saving in personnel. The twin system located in the space between the two units of each pair eliminates long lines of piping. The protective devices and annunciator system also were described. Impulses from the respective relays not only indicate the source of trouble, but also act upon certain safety devices arranged to produce the desired effect upon the governor.

J. E. Stewart (Pittsburgh, Pa.) in his discussion of this subject expressed a belief that the outstanding feature of the Safe Harbor development was the engineering study that had been devoted to it, and the fact that so many of the results of these studies were incorporated in the actual construction.

Another discussion by R. L. Thomas (Baltimore, Md.) interestingly revealed the history of this development from the time of the first individual flow rights, which dated back to 1902, up through the selection and acquisition of the present site. Early economic studies by the regular operating staff without any publicity and without outside aid prior to making of core borings at the dam site resulted in relatively low costs of property and flow rights as well as for preliminary engineering and organization work. The pre-license cost, exclusive of property, amounted to less than one per cent.

In addition to the foregoing discussion of this development, P. M. Hess, station superintendent at Safe Harbor, outlined the operating experience with the major pieces of equipment thus far obtained from the 10 months' period operation.

*Safe Harbor-Westport 230-Kv Transmission Line.*—H. S. Phelps (Philadelphia, Pa.) in his discussion made a comparison between this line and the Philadelphia Electric Company's 220-kv lines which have essentially the same electrical design features. He presented operating data on the latter lines and suggested a comparison of operating results between these lines. He believed such a comparison should make possible the forming of conclusions better than those presently held concerning the influence on line performance of insulator spacing and string length, size and location of ground wires, and phase wire spacing.

C. L. Fortescue (East Pittsburgh, Pa.) discussed the early considerations that entered into the design of this line. He explained that in the design of transmission lines a compromise must be made between what can be done regardless of cost and what can be considered as economically justified. He believed the author had effectively reached such a compromise as indicated by the performance during the past year.

*Safe Harbor Kaplan Turbines.*—E. Brown (Montreal, Canada) discussed this subject and raised questions concerning several points about the paper. One of these concerned the curves in Fig. 6 which he believed showed large differences between the values of $\Sigma$ at which the efficiency begins to decrease and the unit quantity to increase. He believed that the points of increase or decrease were not well defined. The authors' statement that "the value of $\Sigma$, at which efficiency and discharge were found to break, was taken as the cavitation limit for that particular speed, head, and gate opening" seemed to the discusser to imply a much closer agreement between $\Sigma$ values than that shown in Fig. 6.

In connection with the cavitation experiments, J. A. Peck (Boston, Mass.) asked what means were employed to isolate the phenomenon of the efficiency break so that it could be positively attributable to the cavitation rather than to some other coincidental factor, such as a crisis in the flow conditions within the particular type of draft tube in use.

R. E. B. Sharp (Philadelphia, Pa.) discussed the cavitation problem and referred to an installation in Canada that furnishes an interesting example of the ability of a turbine to operate without serious pitting with a value of Σ so low as to result undoubtedly in the formation of continuous cavitation without sufficient pressure to cause the collapse of the cavities. A curve was presented which represented roughly the limit in value of Σ for the usual modern propeller runner designs.

Messrs. L. B. Stirling and J. B. MacPhail (Montreal, Canada) asked if the possible occurrence of pitting in the draft tube was examined by paint tests. The pitting of a painted surface in a model draft tube is believed to be a good indicator of erosion of concrete on the full sized installation. This relation has been proved to be correct in at least 2 cases.

Another discusser, H. S. Van Patter (Montreal, Canada) inquired, in connection with the tests, as to why it was considered necessary to hold the total head constant when varying the suction head and asked if that decision had been confirmed by test results. In other words had tests shown that the cavitation point was affected by variations in total head?

### LOW HEAD HYDROELECTRIC DEVELOPMENTS

L. F. Harza (Chicago, Ill.) in his discussion of this paper questioned the general desirability of using special Kaplan wheels on horizontal shafts, such as shown in the author's Fig. 26. He pointed out that the draft tube problem is complicated, the building width greater, and that high tailwater requires design of the generator room walls for outside pressure, and the use of drainage pumps to remove leakage.

H. E. Popp (Boston, Mass.) discussed this subject from a point of view different from that taken by the author. He did not agree that credit for past accomplishment in the field of economical low head developments was due entirely to European engineers. It was pointed out that the so-called Kaplan turbine in reality is the use of the adjustable-blade runner and its control mechanism in combination with the usual form of scroll case, draft tube, and miscellaneous mechanical details independently developed and perfected by American engineers. He also believed that there was grave danger that overemphasis of some particular phase of design, such as the cavitation problem, might lead to the introduction of costly practises that are not justified by the ends obtained. In this connection he did not agree with the practise to machine and polish all runner blade surfaces in contact with flowing water, especially since this has no effect on efficiency.

J. W. Rickey (Pittsburgh, Pa.) was of the opinion that the future development of hydroelectric projects of low and medium head in the United States depended upon obtaining lower plant cost through greater economy in the design of both plant and equipment. This, he believed, could be achieved only when the manufacturer and the user of turbines adopt a radically different attitude toward the scientific side of concurrent turbine design and laboratory tests.

F. H. Rogers (Philadelphia, Pa.) in his discussion presented considerable of the history of the development of the propeller turbine, in particular, the achievements made in the United States. He referred to the Great Falls development of the Manitoba Power Company undertaken in 1921 when the Dominion Engineering Works, Ltd., proposed I. P. Morris propeller turbines of 28,000 hp unit capacity for a head of 56 ft. At that time a cavitation theory for the propeller turbine was developed utilizing data from marine propeller experience. He also referred to the early work of L. F. Moody, an American engineer, who first demonstrated that for a head range more than double that previously attempted, equal or greater efficiencies with freedom from cavitation could be secured by the use of large areas for the blades.

In connection with this subject R. V. Terry (Newport News, Va.) told of a new type of adjustable propeller turbine now in the process of development. The vanes of the runner are adjusted automatically by the water flow, assuming the most efficient angle for any head and for any load within the capacity of the turbine.

## John Fritz Medal for 1933 Awarded

The John Fritz Gold Medal for 1933 has been awarded to Daniel Cowan Jackling for "notable industrial achievement in initiating mass production of copper for low grade ores through application of engineering principles." The award was made by a board of 16 representatives of the 4 national engineering societies.

Mr. Jackling is the twenty-ninth engineer to receive the John Fritz gold medal, which is awarded not oftener than once a year for notable scientific or industrial achievement without restriction on account of nationality or sex. It is a memorial to the late John Fritz, a leader in the American iron and steel industry; the first medal was awarded to Mr. Fritz in 1902 in celebration of his eightieth birthday. Members of the Institute who have received this medal include: Elihu Thomson (A'84, F'13, HM'28, member for life, and past-president); Guglielmo Marconi (HM'17); Ambrose Swasey (HM '28); Edward D. Adams (A'10); Elmer A. Sperry (M'29); John J. Carty (A'90, F'13, HM'28, member for life, and past-president); Herbert Hoover (HM'29); and M. I. Pupin (A'90, F'15, HM'28, member for life, and past-president). Other John Fritz medalists, no longer living, include: George Westinghouse (A'02); Alexander Graham Bell (A'84, M'84, and past-president); and Thomas A. Edison (A'84, M'84, HM'28).

Mr. Jackling was born at Appleton City, Mo., in 1869 and was graduated from the Missouri School of Mines in 1892. After spending a few years in teaching and in technical work in connection with mining operations he turned his attention to construction and operation of metallurgical works and embarked upon his notable career in that field as a pioneer in mass production of copper from low grade ores. The improvements in the production of copper conceived and originated by Mr. Jackling have resulted in a great increase in the world's production of copper, and a reduction in its cost. The electrical industry, as well as many other modern industries, are greatly indebted to Mr. Jackling for these improvements in the production of copper.

Mr. Jackling was director of explosives for United States government during the World War and in this capacity performed distinguished service. He is also esteemed in many sections of the western United States for his interest in the communities which under his direction have been built up at the properties of which he is the head. He is president and director of several copper mining and related companies. For his public and industrial services he has been honored by the distinguished service medal of the United States Government in 1919, the gold medal of the Mining and Metallurgical Society of America in 1926, and the William Lawrence Saunders gold medal of the American Institute of Mining and Metallurgical Engineers in 1930.

## Noted Engineer Honored on Retirement

Robert Ridgway, chief engineer of the board of transportation of the City of New York, N. Y., retired on November 1, 1932, after having worked for the city for 48 years. On the date of his retirement he was the guest of honor at a dinner given at the Engineers' Club by 105 leading engineers of the country. A feature of this event was Mr. Ridgway's tribute to those who had worked with him during this period.

Mr. Ridgway was born in Brooklyn, N. Y., in 1862. Although he secured his education in the public schools of Brooklyn and at home, he has received honorary degrees of M.S. in C.E. from New York University in 1915, A.M. from Harvard University in 1925, and doctor of engineering from Lehigh University in 1929. After spending 2 years with the Northern Pacific Railway as chainman, rodman, and leveler in Montana and Wisconsin, he entered the employ of the aqueduct commission of New York City in 1884 and remained with the city from that time until his retirement. During this period he has supervised the construction of many of the city's subways and elevated lines and built many of the tunnels and aqueducts which have been of such tremendous importance to the development of this city. He has also been a member of the Chicago Traction and Subway Commission, chairman of the board of engineers for the Transbay Bridge, San Francisco, Calif., member of the Colorado River Board of the United States government, Hoover Dam Project, consulting engineer for the Japanese Government Railways and to the cities of Tokio and Osaka, and consulting engineer on subways for the City of Chicago. Mr. Ridgway is a member of several engineering and scientific societies and is a past-president of the American Society of Civil Engineers.

# Unemployment Relief Plans Throughout Country Progressing

CONSIDERABLE experience in means for alleviating unemployment and providing relief to the more destitute members of the engineering profession was gained during the winter 1931–32 by many Sections of the Institute. This experience is proving of great assistance in the formulating of plans for relief to engineers during the coming winter, and should make the 1932–33 efforts even more effective than those of last winter. A summary of the activities of some of the Institute's Sections during the past winter was given in ELECTRICAL ENGINEERING for November 1932, p. 809–13.

For the coming winter, most of these sections report that the activities planned are similar in scope to those of last year, although changes are being made in the methods of securing work and of providing financial assistance. Sections generally have found that the conducting of surveys of industrial organizations in their community, for the purpose of determining positions which might be filled by men on the unemployed list, have produced meager results. However, where an energetic campaign has been conducted to create new positions in industry and to "sell" business organizations of all sorts, including the wholesale and retail distributing units, even department stores, on the idea of using engineers in positions for which it was not previously realized that they were valuable, the results have been surprisingly successful. The possibilities of extending this type of work are realized by many of the Sections, and others doubtless would do well to give consideration to its possibilities.

In most localities the Institute Sections are cooperating with the local Sections of the other engineering societies in assisting the local civic organizations that are providing relief to the entire community. One of the most important lessons that was learned last year in the localities where this type of relief was attempted is that the engineers must, themselves, remain active on the civic relief groups, in order to insure that the members of their own profession secure their proper proportion of relief. This has been found to apply not only to providing employment, but also to the provision of financial assistance to those for whom no employment is found. The importance of this phase of the work needs to be emphasized in many communities. The local civic bodies carrying on the general relief work are almost universally capable and anxious to be impartial. However, activities of other groups require that out of loyalty to their profession, Sections of the Institute should secure representation on these civic bodies, and should add their voices to secure a fair distribution of relief to all industrial groups.

In the campaign for funds to be used this winter, an effort is being made in several communities to increase the number of contributors to these funds, rather than to increase the amount of individual contributions. The fairness of this plan needs no comment here. Willingness is being shown also by those still employed to cooperate in the plans for spreading work among the largest number possible and thus reduce cases of extreme hardship. The larger cities, of course, are the most active in providing unemployment relief because it is in those communities that the greatest need occurs. It is in the larger cities, however, that the greatest difficulty is encountered in making contact with needy cases. In the smaller communities, especially those not having many industries, concerted action by engineers has been found almost unnecessary, partly because more intimate contact between members of these communities is possible and partly because those requiring assistance are more likely to be aided by their friends and acquaintances.

Letters have been received from many Sections of the Institute, outlining the plans for the coming winter. Some of these are summarized or printed in full in the following paragraphs in the hope that a circulation of these ideas may be of assistance to other Institute Sections.

## NEW YORK CITY

In the metropolitan area of New York, N. Y., the local Section of the Institute is acting through the Professional Engineers Committee on Unemployment, the activities of which last year were presented in some detail in ELECTRICAL ENGINEERING for November 1932, p. 809–11. Activities for 1932–33 were started by the chairmen of the New York Sections of 4 national engineering societies getting together and deciding upon the work to be done. An organization was formed with Rear Admiral Frederic R. Harris, retired, as general chairman. H. deB. Parsons, who was general chairman last year, is serving this year as chairman of the advisory committee. As last year, United Engineering Trustees, Inc., is acting as treasurer. The working committees for the coming year are as follows: *finance committee,* T. F. Barton (A'12, F'30), chairman; *relief committee,* Ole Singstad, chairman; *publicity committee,* E. E. Dorting (A'13, M'22), chairman; and *clearance committee,* Alfred D. Flinn, chairman.

One change from last year is in providing for contributions to be paid in weekly payments extending over a period of 20 weeks, in addition to the alternative of making donations in 5 monthly payments as was provided last year. Following are excerpts from a statement made by the chairman of the New York Section of the Institute.

"The incoming committee is impressed with the organization developed last year, and realizes fully the successful outcome of their efforts in providing relief to engineers in the [N. Y.] metropolitan territory during 1931–1932. The plans for this year's operations will not depart from those of last year, and with the early start made we expect to accomplish as much as last year, and hope to do even more, since we are convinced that the demand this year will exceed that of last year. The united effort of local sections of 4 engineering societies in this work results in a unity of purpose and in efficiency and economy in handling the work. We feel that we are able to accomplish our objectives by providing:

"1. A suitable place for the registration of unemployed engineers, both members and non-members of the societies.

"2. An organization for the soliciting of funds to be used entirely for relief purposes.

"3. Establishing contacts with other relief committees in the community and in this way obtain temporary employment for a large number of the men registered with us.

"Our registrants are primarily interested in obtaining work, and it is gratifying that by far the larger part of our relief comes as a result of obtaining employment for these men. Last year for each dollar expended by the Professional Engineers' Committee on Unemployment in direct relief, a total of approximately $6 was paid to our registrants for work created by other relief organizations in the community and paid for by them. (Editor's Note: Efforts of the P.E.C.U. in securing for engineers a proper proportion of the relief afforded by the Emergency Unemployment Relief Committee of New York City has been an important phase of the work and is one that can be duplicated easily in any community.) This year we are assured of the hearty cooperation of other relief agencies, and if possible this year we should like to increase the 6:1 ratio to an even higher figure.

"Contributions from our members and friends to date are in line with last year, and we are confident that our membership with the full realization of the problem at hand will respond liberally so that the total amounts collected for the year will be gratifying, not only to the committee but to the membership at large."

## PLANS OF SOME OTHER CITIES

Excerpts of letters received from some other of the sections follow. In presenting this information an effort has been made to include suggestions for the coming year. It is felt that records of last year's accomplishments, however important, were covered to a considerable extent by the article in ELECTRICAL ENGINEERING for November 1932, p. 809–13, previously referred to.

The relief program in Boston, Mass., undertaken by the Emergency Planning and Research Bureau, Inc., was reported in some detail in ELECTRICAL ENGINEERING for November 1932, p. 811–12. The following statement of the Honorable Joseph B. Ely, Governor of Massachusetts, indicates the value of this work: "Several of the state boards lack the necessary funds for obtaining information which is very desirable for the conduct of their work. The Emergency Planning and Research Bureau has taken over this work, and has already furnished the state agencies valuable data which would not otherwise have been available." Of interest also is the following statement of Philip Cabot, head of the department of public utilities, graduate school of business administration, Harvard University: "You (the members of the engineering and architectural societies of Boston) have recognized better than others that the cost of planning is far less than the expense of correcting errors and of living with mistakes; that the losses imposed by uncoordinated, sporadic, and parochial development will not long be tolerated, and that when the time comes for broad planning, facts must be available on which it can be based. You have grasped the fact that slack times should be used for compiling and interpreting facts which will be needed in busier periods. You have properly confined your work to the collection of those facts which will be essential to those organizations which in the future must plan the development of this crowded district."

From the Philadelphia Section: "Our experience indicates a campaign for raising funds by the affiliated societies for the purpose of relief should be carefully approved and an organization established thoroughly in accord with the project before launching into the campaign. One of the chief difficulties is personally contacting the membership. Taking Philadelphia for illustration, the members reside throughout Philadelphia and the suburbs, part of Pennsylvania, New Jersey, and Delaware. Subscription cards were prepared with the name and address of members and for the A.I.E.E. were arranged by firms and by geographical location, so as to facilitate the work of soliciting on the part of those members on the fund raising committee. It was not possible personally to contact the membership outside of Philadelphia and the immediate suburbs. In these cases, an appeal was made by letter. The most effective way to raise funds is through official endorsement and solicitation being carried on among the technical employees by the firm; next is by personal contact, the smallest contributions being received in amount as well as in number by letter."

Also, the following is taken from an article describing the work of the Philadelphia Technical Service Committee (see ELECTRICAL ENGINEERING for November 1932, p. 813 and July 1932, p. 526): "Too little emphasis ordinarily is placed upon the necessity for providing useful work for these unemployed to perform along the general lines of their experience and capabilities. After a man has been out of work for an extended period and has tramped the streets in a useless endeavor to find a job, he begins to lose confidence in himself and in his profession, and he needs the kind of job which requires him to use his brain and to employ the experience which he has acquired in previous positions."

Funds raised by the Pittsburgh Section, totaling $646.25 for the months of June to October, inclusive, 1932, are turned over to the Engineers' Relief Committee of Pittsburgh which, as of the first of November 1932, had raised approximately $11,000. Distribution of these funds, as of May 28, 1932, was reported in ELECTRICAL ENGINEERING for November 1932, p. 813, and is divided between loans and contributions to individuals. It is stated that "it is planned to continue the work during the winter in much the same way as it has been handled in the past. The relief work has done a great deal of good, although it is on a small scale, since it has helped men who would probably not have received help through the ordinary relief channels."

From the Dallas Section: "The Dallas Section has no formal program of unemployment relief activities to be undertaken during the coming winter. It is not thought that a formal program here can be justified, because of the relatively small number of unemployed engineers and of the comparatively few opportunities in this Section's territory for additional technical employment. The members of Dallas Section as individuals cooperate with the local civic relief organizations, which have under way now a drive for funds."

From the Spokane Section: "Our program for unemployment relief for the coming winter will be the same as that practised last year. This consisted of cooperating with the local group of Associated Engineers. This organization is comprised of engineers of all branches and holds weekly noon-day meetings. Their unemployment committee is composed of a representative from each of 4 local sections of national societies. This committee has functioned satisfactorily in the past. It has been instrumental in locating jobs for numerous men. Its members have contacted many employers to whom they have told the story of why engineers should be employed in almost any line of work because their training as engineers has fitted them for work over a broad range. At present there are practically no unemployed electrical engineers who are members of this section. They have found work in various other lines, especially commercial."

### INDEPENDENT ACTION TAKEN BY SAN FRANCISCO SECTION

From the San Francisco Section: "Our activity in San Francisco has been purely within our own Section. The other societies in San Francisco have so far as I know taken care of their own members. This plan has worked very well here. It is in keeping with the suggestions of President Hoover as regards national relief and that is that each community take care of its own needy. It has proved very efficient and without waste. The collection of the relief fund is based upon an administrative period of 6 months. Actual experience in the operation of the fund during the first 6 months showed a surplus and it was decided to carry this surplus over into the fall and winter period rather than return it to the original donors, this on the theory that the unemployment situation would become more acute at that time. Accordingly, the fund was divided into 2 parts, a small amount being held for current necessities and the balance placed in a savings account. No attempt was made to collect delinquent pledges, and voluntary contributions were discouraged. We, therefore, find ourselves in a position to enter the fall and winter period with a reserve fund on hand, and anticipate no difficulty in meeting possible drains upon the fund through a revival of the pledges and voluntary subscriptions. We are particularly fortunate in San Francisco in the rather close affiliation among the members of the 4 principal engineering societies; for instance, through the interlocking directorship of the San Francisco Branch of the Engineering Societies Employment Service. Unless the situation proves exceedingly difficult, we look forward to carrying on through the winter season with a fair degree of success through the operation of the relief fund. The funds are in the hands of a trustee and are administered separately from the funds of the San Francisco Section of the A.I.E.E."

From the Atlanta Section: "The Atlanta Section was instrumental in having an executive committee consisting of the chairmen of the electrical, mechanical, and civil engineers and architects to consider this (unemployment) problem. This executive committee has been in operation approximately 9 months, and has been instrumental in assisting engineers to find employment within our district. If an engineer needs assistance the matter is brought to the attention of this committee and a very definite effort is made by us to find part time employment or some other means of assistance. The situation in regard to engineers in Atlanta and Georgia has not been as severe as in other states. Most of the firms in this vicinity have cooperated on the basis of sharing the engineering work. For instance, a company employing quite a number of engineers have reduced their work to a half-time basis so that as many engineers as possible could be given a livelihood. Also, a number of engineers that were released have found employment in other lines within the state. I do not mean to imply that we are in a position to absorb additional engineers in this district, but do feel that we have been instrumental in assisting engineers in keeping in employment. We have not given very much publicity to this activity rather depending upon the members of the Societies mentioned above to bring to our attention worthy cases. So far we have confined our assistance to members of the societies mentioned above, but in case of a worthy cause we would also assist an engineer not affiliated with one of these societies."

### 4 PER CENT LOANS MADE BY PORTLAND SECTION

The Portland Section, as outlined in ELECTRICAL ENGINEERING for November 1932, p. 813, is working with the Oregon Technical Council in making loans to engineers at 4 per cent interest. Further information from this Section follows: "At present we are soliciting subscriptions for funds to be used for loans this winter as our balance is getting low and only one note has been repaid. Last year we had relatively few large subscriptions, but this year we are trying to get a large number of small subscriptions. The local section of each founder society solicits the funds and pays all expense of the solicitation, while the administration and expense of handling this fund is paid by the Oregon Technical Council. In conjunction with this loan fund, we have an employment committee which has been successful in placing many engineers in such places as timekeeper, foremen on construction jobs, watchmen, and many other jobs."

From the Milwaukee Section: "All of the work of the Milwaukee Section of the A.I.E.E. has been in connection with the work done by the Engineers Society of Milwaukee, with which we are affiliated. The Engineers Society has appointed a special investigator to collect information on the unemployment of engineers, through questionnaires among the members and through personal solicitation regarding the possibilities of work among employers. The result of this work has been to show that approximately 150 engineers are without employment at the present time. A recent secondary questionnaire determined that, among these 150, only 2 are in serious distress. These men are being helped by monthly appropriations from the funds of the Engineers Society. There seems to be little prospect of increasing the employment in the near future from industrial sources. However, a considerable amount of municipal and government work is under contemplation, and it is expected that some placements will be possible in this manner. It appears that the depression has in many cases required engineers of a high grade and of good professional standing to take up work in other lines—in many cases with marked success. This may mean a permanent displacement of men of this type into other lines of work."

From the Utah Section: "The membership of this Section numbers about 53. At present it does not seem advisable for it to take up independent relief work. Engineers in this section of the country are individually joining in the general relief movement carried on through cooperation of societies, clubs, and local groups."

### FEWER UNEMPLOYED ENGINEERS LISTED IN COLORADO

From the Denver Section: "The Denver Section, as the other Colorado sections of 4 national engineering societies, has combined its efforts toward relief of unemployed engineers with the Colorado Engineering Council, in the same manner as done last year. Pledges to the Citizens' Unemployment Committee are marked 'For relief of engineers' and funds so derived are made available to the Colorado Engineering Council's relief committee. Approximately 190 engineers and draftsmen are listed with the committee at present. This is less than at the same time last year, although in the late winter the number reached 247 last year, with an increase anticipated this year. Approximately $10,000 was distributed in this way last year. We hope that the funds made available in this campaign will be greater. The men have been employed on engineering work which, if resulting in construction, will produce employment for a large number of men, such as flood control, city drives, and parks. Direction of this work has been done by prominent engineers who have donated their services. Men are paid $3 a day employed, and the work is rotated to distribute the benefits as far as possible."

From the Oklahoma City Section: "We have read of the activities of various Sections in unemployment relief work in the March and November 1932 issues of the ELECTRICAL ENGINEERING and are deeply impressed by the efforts described and would be glad indeed to contribute to the general fund of information had we any experience with the problem. As a matter of fact, the situation in this Section seems not at all comparable to that in the more populous centers. Due, no doubt, to the fact that practically all of our members are in the employ of utility organizations which have followed the policy of apportioning the available work on a reduced time basis, thus avoiding the distress occasioned by dropping men from payrolls. There is not a very large membership in the other engineering societies in this locality and thus far, conditions do not seem to warrant the establishment of any particular program of relief work. This is the consensus of opinion of our executive committee. We believe that, in general, our membership is favorable to still further reductions in individual incomes if necessary to avoid total unemployment. There is, of course, a limit to the extent to which this practise may be carried and it is entirely possible that we may eventually find it necessary to give some special consideration to relief work."

### STATE FUNDS USED IN CHICAGO

From the Chicago Section: "The Chicago Section in cooperation with the other engineering societies is actively working on the following program. State funds have been provided for unemployment relief, part of which are devoted to direct relief such as supplying food and other essentials, and another part to the payment for actual work performed for municipalities and other public bodies. Work of the latter nature has so far been principally confined to common labor, but the engineering societies are now working on 2 specific phases of a program which it is expected will make it possible to care for many, if not all, of the engineers in need of relief during the coming winter. The first phase of the above project consists in finding types of work suitable for engineers, such as making traffic studies, bringing engineering records of the city and other public bodies up to date, all of which cannot be done with the present employed forces. The second phase consists of finding the engineers who are in need of help, making the necessary classification, and seeing that they obtain work of a suitable nature, as outlined above. In addition to the above, certain of the local sections of the engineering societies are making direct loans to needy members, although the extent of this work and the amount of money distributed is relatively small."

**Electragists Revert to Original Name.**—At the annual meeting of the Association of Electragists, International, held in Kansas City, Mo., October 10–12, 1932, it was decided by unanimous vote to change the name of this association to the National Electrical Contractors' Association. This latter name is the one under which it was organized 31 years ago. The trademark "Electragist" will still be used in conjunction with the association name as identification of membership.

**Report on Banking Issued.**—After an exhaustive study of the banking situation by its staff experts, the National Industrial Conference Board, Inc., has issued a report under the title "The Banking Situation in the United States." One of the conclusions reached by this study is that the various measures recently enacted by Congress for the relief of the financial situation in the United States are for the most part temporary expedients and that while some of them may contribute in a certain degree to the permanent improvement of banking conditions, it would be an illusion to conclude that they are capable of providing a lasting solution of the American banking problem. Many aspects of the banking situation are discussed, and the significance of the startling developments in the field of banking that have taken place during the last 2 years are set forth lucidly in this report.

## World's Fair Electrical Group Dedicated

The electrical group of Chicago's 1933 World's Fair—A Century of Progress Exposition—comprising the radio hall, communications hall, and the electrical building, was dedicated on Wednesday, October 12, 1932, under the auspices of the Electric Association of Chicago. B. E. Sunny (A'03, F'13) former president and chairman of the Illinois Bell Telephone Company, and director and member of the executive committee of the General Electric Company delivered the address of dedication. Mr. Sunny is a trustee of the 1933 Exposition and was a director of the World's Columbian Exposition of 1893. W. O. Batchelder (A'08), president of the Electric Association of Chicago, presided at the ceremonies. Rufus C. Dawes, president of a Century of Progress Exposition, spoke on behalf of the fair.

The electrical group is a huge sickle-shaped structure nearly $^1/_4$ mile long which rises on Northerly Island and faces a beautiful lagoon opening into Lake Michigan. A bridge connects it with the Hall of Science which is located opposite on the mainland. The story of the development of electricity for mankind's uses which has occurred in the century which the exposition will celebrate will be unfolded by means of moving, animated exhibits in this group of buildings. Manufacturers of electrical machinery, equipment and supplies, producers of electrical devices of all descriptions, radio manufacturers, and companies providing the nation with telegraph and telephone service have already contracted for extensive blocks of space in the electrical group and are developing their exhibit plans.

**Sale of Electrical Goods in Southwest Analyzed.**—The answer to the question of who gets the consumer's dollar spent for electrical equipment and supplies in the Gulf Southwest hardware trade is one of the interesting sidelights brought out in the Department of Commerce's newest regional commercial study "Hardware Distribution in the Gulf Southwest." This publication offers to interested manufacturers and distributors a thorough study of the wholesale and retail structure of the trade in this territory. Among the findings brought out are that approximately 28 cents of each dollar spent for electric wiring supplies by customers of the hardware trade is retained by the retailer, 14 cents goes to the wholesaler, and the remaining 58 cents goes to the manufacturer. In small electrical applic ances it is revealed that the split-up is 32 cents to the retailer, 12 cents to the wholesaler, and 56 cents to the manufacturer. Other products show different distributions. The average gross profit margin of electrical wiring supplies was found to be 19 per cent; small electrical appliances, 18 per cent; mechanical refrigerators, 33 per cent; radios, 22 per cent; and vacuum cleaners, 21 per cent. Copies of the report may be obtained at 40 cents each from the Superintendent of Documents, Government Printing Office, Washington, D. C., or from district offices of the Bureau of Foreign and Domestic Commerce in principal cities of the country.

## Volume Issued on Geophysical Prospecting

"Geophysical prospecting methods are, in final analysis, simply means of geological surveying. Almost every variation in physical properties of rocks, minerals, and ground waters gives rise to anomalies which under favorable conditions might be measured and used to trace formations, contacts, and structures...." This statement is contained in the foreward of "Geophysical Prospecting, 1932," a new volume on a new science, published by the American Institute of Mining & Metallurgical Engineers. The cloth bound volume can be secured from this organization at 29 West 39th Street, New York, N. Y., at a cost of $5 postpaid in the United States.

The contents of this work include: 2 papers evaluating the geological utility of various geophysical methods; 4 papers containing descriptions of the application of electrical geophysical technique to the study of geological problems of a type to interest civil engineers; 2 papers describing the use of magnetic methods for investigating subsurface conditions; a discussion of the effect of moisture in rocks and soils on their electrical conductivities; a description of the construction and uses of geophones; and numerous other papers dealing with special phases of electrical, magnetic, seismic, and gravitational methods in geophysical exploration.

**Power Use on Farms Increasing.**—An analysis of the use of power machinery on the farm is presented in a recent issue of the bulletin of the National Industrial Conference Board, Inc., New York, N. Y., which states that the hand methods formerly in use required about 60 hr of labor for one man to harvest and thresh an acre of wheat, whereas with the self-binder and stationary threshing machine, the time was cut to from 4.5 to 8 manhours, and with the coming of the "combine," the manhours were reduced to from $1/2$ hr to $1^1/2$ hr. The gain in efficiency per worker achieved by these mechanical aids is from 4,000 to 12,000 per cent, with a consequent labor displacement of 97.5 to 99.2 per cent. These figures are based upon the records of the principal wheat growing states of this country, the greatest gain in efficiency being noted in California. The continuance of this trend is pointed out in the bulletin, indicating the possible elimination at some future time of wheat farming where such machinery is not used. Although tractive power represents the chief use of mechanical power in farming operations, there has been a considerable use of electricity in farming where central power stations are accessible.

**Accidents Reduced by Highway Lighting.**—During the past 18 months, 2 main highways in Schenectady County, New York State, have been illuminated at night by highway luminaires. During this period the 2 highways have had 42.3 per cent fewer night accidents than during the preceding 18 months, and 21.2 per cent fewer day accidents. The emphatic reduction in night accidents, which is double the improvement in day accidents, doubtless is due to the installation of highway lighting, as other road conditions have remained unchanged.

## Hoover Dam Cableways Ordered

In connection with the construction work at Hoover Dam, the Six Companies, Inc., recently awarded contracts for 5 20-ton cableways. These cableways will be used to raise excavated material from the canyon, place concrete in the dam, and handle equipment and materials. Two cableways with moving towers running on tracks benched on both the Nevada and Arizona sides, with spans of 2,580 ft each, will serve the spillway area. The dam site will be covered by 2 cableways of similar type, but with spans of 1,380 ft each. The fifth cableway will be of the radial type, with a 1,365 ft span, and will cover the lower portals of the spillway and penstock tunnels.

Six contracts have been awarded for the various parts of this equipment. The motors and control equipments are now being shipped from the East Pittsburgh works of the Westinghouse Electric and Manufacturing Company and include 5 500-hp 585-rpm main hoist and trolley motors for the 5 20-ton cableways, 9 motors ranging in size from 75 to 150 hp for moving the cable towers sideways, and 33 control boards. All motors are of the wound rotor type, operating from 2,300-volt 3-phase 60-cycle power, and equipped with full magnetic reversing plugging control.

**Manual on Endurance of Metals Available.**—In 1927 the Engineering Foundation published a "Manual of the Endurance of Metals under Repeated Stress" in which the views and data upon the fatigue of metals were summarized for designers, inspectors, and testing engineers. The Engineering Societies Library, 29 West 39th Street, New York, N. Y., has acquired the remaining stock of this work and will be glad to send a copy to any one interested, upon receipt of 25 cents to cover shipping costs.

## Montefiore Award for 1932 Announced

The George Montefiore Prize, which is awarded triennially for articles published during the 3 years preceding the award, has been determined for this year by the jury which met at Liege, Belgium, October 1 and 2, 1932. The prize, which this year amounted to 21,500 fr., has been divided. Three articles were chosen: these are by L. Barbillion, engineer, professor at the University of Grenoble; A. Guilbert, Doctor of Sciences, engineer in Paris, and C. J. van Griethuysen, engineer at Marcinelle. ELECTRICAL ENGINEERING for February 1932, p. 135 carried an announcement of this award, inviting the submission of articles to the jury.

The award is for the best original works contributing to the scientific or technical advancement of electricity. The authors may be from any country. The prize is administered through the Association des Ingenieurs Electriciens, or a national electrical society of Belgium. This association is an outgrowth of the Institut Electrotechnique Montefiore, which is attached to the University of Liege.

The jury, under the direction of Omer De Bast, director of the Institut Electrotechnique Montefiore, is composed of 10 electrical engineers who are well known in the electrical industry in Belgium and other countries, and includes as a member A. E. Blondell (A'05, HM'12), professor at the École National des Ponts et Chaussees of Paris. The next meeting will be held in 1935 at which a prize of 22,000 fr. will be given.

**Chromium Plating Patent of Doctor Fink Upheld.**—Validity of the patent of Dr. C. G. Fink, professor of electrochemistry at Columbia University, New York, N. Y., covering commercial chromium plating, was sustained by an unanimous decision of the U.S. Circuit Court of Appeals for the second circuit, in which all claims of the inventor to his basic methods for chromium plating were upheld. The suit was brought by United Chromium, Inc., holder of Doctor Fink's patent, against the International Silver Company, which based its defense upon the research performed by the U.S. Bureau of Standards, the Eastman Kodak Company, and the Westinghouse Electric Manufacturing Company. The Court of Appeals held that this work failed to anticipate the work of Doctor Fink, and that the patent provided the method with which "for the first time the art could turn out chromium plating with certainty." The work of Doctor Fink was revealed as one of the great achievements of modern chemical research. For many years chemists attempted to solve the problem of plating metals with chromium, but without success. Doctor Fink worked at the problem, and after making numerous experiments he finally evolved a basic method to plate objects with a uniform and adherent coating of chromium. He found that the chromium particles could be deposited successfully in a durable coating only in the presence of a catalytic agent in the plating bath. Proper concentration of this catalyst in the plating bath eliminates erratic and uncertain results in chromium plating.

## Electrical Engineers Increase in Number

A comparison of 1920 and 1930 census figures gives a vivid picture of changes that have been taking place in occupational distribution. This data which can be obtained from the Superintendent of Documents, Washington, D. C., for all occupations and sections of the country, has been summarized in a recent bulletin of the Personnel Research Federation, 29 West 39th St., New York, N. Y. The following paragraph is taken from this bulletin:

"It seems that many more men have been entering professional careers. Only in the profession of veterinary surgery was there a substantial decline. The supply of male dentists increased a trifle faster than the total working population, and of physicians and surgeons a little more slowly; but the number of women in these professions definitely decreased. Most spectacular of all, there were more than twice as many electrical engineers in 1930 as in 1920. Stock brokers and insurance agents also more than doubled in number. The transfer of functions from home to shop is reflected in the data regarding men and women workers in cleaning, dyeing, and pressing establishments. The 1930 figures are 389 per cent and 473 per cent, respectively, of those from 1920."

The data given in Table I summarized the changes in the engineering profession over this 10-year period. In addition to the males shown in this table, there were in all occupations in the United States 10,752,116 females, 127 per cent of the number employed in 1920.

Table I—Comparison of 1920 and 1930 Census Figures for Engineers

| | U. S. A.—Male | | N. Y. C.—Male | |
|---|---|---|---|---|
| | 1930 | % of 1920 | 1930 | % of 1920 |
| All occupations | 38,077,804 | 115 | 2,324,599 | 126 |
| Civil engineers and surveyors | 102,057 | 158 | 6,782 | 141 |
| Designers, draftsmen, and inventors | 93,518 | 149 | | |
| Electrical engineers | 57,775 | 214 | 5,475 | 223 |
| Mechanical engineers | 54,338 | 141 | 4,120 | 121 |

# Letters to the Editor

CONTRIBUTIONS to these columns are invited from Institute members and subscribers. They should be concise and may deal with technical papers, articles published in previous issues, or other subjects of some general interest and professional importance. ELECTRICAL ENGINEERING will endeavor to publish as many letters as possible, but of necessity reserves the right to publish them in whole or in part, or to reject them entirely. STATEMENTS in these letters are expressly understood to be made by the writers; publication here in no wise constitutes endorsement or recognition by the American Institute of Electrical Engineers.

## Rudolph Frederick Schuchardt —An Appreciation

*To the Editor:*

On October 25, 1932, there passed from among us one of God's noblemen, Rudolph Frederick Schuchardt, a past-president of the American Institute of Electrical Engineers, and chief electrical engineer of the Commonwealth Edison Company.

Modest, courteous, lovable, a clear thinker, an able organizer and executive, Mr. Schuchardt, in spite of his multitudinous duties and responsibilities was never too busy to help a friend or serve his fellow man.

For the past 10 years, his life was permeated with ill health and saddened by the tragic loss of his beloved wife, but he refused to be crushed by fate and during this period, faithful to his high ideals, rendered conspicuous service. Engraved upon his heart was the gallant motto, "Ich dien."

Honored by his friendship for a quarter of a century, I wish to add my tribute to the memory of so fine a gentleman, so lovable a friend.

Very truly yours,
H. L. WALLAU (A'00, F'13)
(Chief Electrical Engineer,
Cleveland Electric Illuminating Co., Cleveland, O.)

## Brass Tacks in Economics

*To the Editor:*

The article under the title "Brass Tacks in Economics" by David Cushman Coyle in ELECTRICAL ENGINEERING for October 1932, p. 712–3, is one of the most suggestive yet printed in the symposium "Has Man Benefited by Engineering Progress?" In a few words it points out the principal problems still to be solved by our Western civilization.

Unless some such solution is seriously undertaken during this generation or the next, it is most probable that some form of socialism or communism will be adopted by most Western nations or by a league of all the nations which are predominantly Caucasian.

If the present Russian experiment proves successful within the next few decades, then a league of this kind will probably be formed at a much earlier date. Once the masses of the Western nations realize that the masses of Russia have reached a standard of living equal to or approaching theirs, without the savage competitive system of the capitalistic world, it would be easy for the leaders of the movement to obtain sufficient following for the establishment of a similar system, either by peaceful and legal methods or by revolution. If the 200,000,000 Russians are living happily without unemployment or idleness, with ample time for recreation and with all the luxuries which we Westerners consider necessities, if they have no arrogant multi-millionaires, no powerful captains of industry, no ruthless commercial warfare, no crowding of the weak by the strong, it will not be difficult for the Western people to realize that there is a new theory of political economy which may be nearer the ideal state than that under which they live.

It seems to me, however, that to carry out Mr. Coyle's suggestion it would be necessary to overcome 3 almost insurmountable obstacles. The first of these is the usual inefficiency and the frequent corruption of most government channels. If heavy taxes on large incomes are collected and the proceeds spent in public and semi-public construction, the collection and the expenditures must be in the hands of a political bureaucracy. Can we depend on the incorruptibility of the members of this bureaucracy and on the ability with which their work will be performed? In view of the corruption and inefficiency so frequently found in our national, state, and municipal administrations, is it possible for any thoughtful man to believe that with our present methods of electing our representatives, our officials, and our judges, these taxes will be collected fairly and economically and spent efficiently and honestly? The first step, then, must be the improvement of the morals of our officials, and as their morality is but a reflection of the morality of the citizens, we must begin by improving the morality of the citizenship. This lack of morality is probably due to the complete breakdown of our religious systems which are the foundations of our morality. If all that the citizens do toward living a better life is to give lip service to their religious leaders on Sunday and act so as to keep just within the law on other days, then little can be expected of real human progress. It would seem, therefore, that the first step required to insure the success of the proposed plan would be to develop a high sense of moral integrity in the citizenry and that little can be gained until that is done.

The second problem which seems difficult to solve is how to give a suitable incentive to inventors and promoters, and how to obtain the advantages of quantity production, of large research and development laboratories. If we had had no large accumulations of capital or rather if the inventors, promoters, and financiers had not seen the possibilities of obtaining great wealth and power, we probably would not have been able to obtain many of the benefits of the present machine age. These inventions may not have served to develop greatly the spiritual aspirations of the human soul but the railroad, the telegraph, and telephone, the dynamo and the internal combustion engine, the aeroplane, the cinema and the radio, have done much to change our world and this scientific and mechanical progress has undoubtedly had considerable effect in the elevation of the human spirit. But many of these things would not have been possible without capital and without the spur of the possible wealth, glory, and power to be attained if successful. Similarly, untold wealth has been lost in trying to develop inventions which have proved unsuccessful, and for that reason it would seem that substantial rewards should be permissible for the adventurers in the fields of science and invention.

The third problem is the necessity of having a union or league of all Caucasian nations before any such system can be put in effect, because no plan of this nature could be successful unless it could be carried out simultaneously in the other nations with which we have to live in this small planet, or at least in a substantial part of the nations which are generally included in our European civilization. As a matter of fact, all the peoples of the world should form part of this federation, but probably the experiment could be properly tried with fair chance of success if, at first, all the basically Caucasian nations would join in it, leaving to the others the opportunity of joining it later. Without practically universal acceptance, the interference from the outside, where institutions of the purely capitalistic, competitive type still ruled, would make the plan unworkable.

Very truly yours,
GUSTAVO LOBO (A'01, F'12)
(President and Treasurer,
Kelvin Engg. Co., Inc.,
New York, N. Y.)

## Too Much Investment Money!

*To the Editor:*

In the October 1932 issue of ELECTRICAL ENGINEERING, p. 712–3, David Cushman Coyle makes the direct statement that there is too much investment money. His whole article, "Brass Tacks in Economics" seems to be based on that statement, and yet he makes no attempt to support it with evidence. We have repeatedly heard the same claim before, but no attempt is ever made to prove it. This is particularly surprising to any one who has had experience in trying to sell equipment. Everywhere we meet the same statement from purchasers, that capital is not available.

If there were too much investment money we should expect that it would appear as a demand for investment securities such as high grade bonds. An excess of investment money must result in a low rate of interest on investment securities, and if the rates are compared for a period of years, we find 6 times this century when these rates dropped decidedly. These years were 1905, 1909, 1916, 1922, 1927, and 1930. If this excess of investment money caused poor business, we should expect that each of these times depression would have followed. Instead every time at least a year of good business followed, with the exception of 1930 in which case it is easy to find reasons why it did not.

Now if we turn to the peaks of interest rates on investment money, which came in the years 1903, 1907, 1913, 1915, 1918, 1920, 1923, 1929, and 1932, we find only one case, the war year 1915, in which the business was good for the following year.

There is other evidence to show that there has never been an excess of investment money in this country, but this simple comparison of the interest rates with business conditions should be enough to demonstrate that the cause of our present troubles is not a surplus of investment money. Some people have been deceived by the low rates of interest of bank loans. These low rates are never given on investment money, but on temporary reserves, on money which may be temporarily loaned on the most liquid securities, but which the holder does not desire or does not dare to invest.

Others have been deceived by the large amounts of wasted capital into thinking that there has been too much. It is not difficult to find cases of poor families spending on some useless luxury the money which they needed for food. We may think that a person who would buy a radio must have an ample surplus, but we know that often that is not the case. And in investments, money has been spent in overexpansion in times when others had difficulty in securing money for needed developments. When a speculative mania is under way, people will throw away what they need, and investors are no different in this respect from the ignorant.

1929 was a year of wasted capital from every side. Gambling profits was consumed in luxuries. The public mortgaged their future for immediate consumption. And perfectly useless business expansion took place. Each caused a loss of investment money, and we are still suffering from that loss. No business revival can take place until a larger proportion of earnings are turned into investments.

Very truly yours,
A. W. FORBES (A'12)
(Forbes & Myers,
Worcester, Mass.)

## Consumption, Production, Distribution

*To the Editor:*

The report of the American Engineering Council committee on "The Relation of Consumption, Production, Distribution" (see ELECTRICAL ENGINEERING for June 1932, p. 373–7) fits so many of the facts that it must contain a very large element of truth. With relatively no foreign capital, funds were available for so much plant expansion from 1923 to 1929 that many engineers and economists regarded our industrial plants as generally overexpanded while during the same period enormous sums were also used to finance the purchase of our products and for speculation.

Simple theories usually require modifications, however. Further study may show that a defective mechanism for controlling the rate and use of savings was the underlying cause of the depression. According to the classical theory of diminishing returns, the excessive diversion of purchasing power to capital uses is controlled by the diminishing returns on additional increments of capital. Why has this mechanism of diminishing returns failed to prevent excessive savings? May I suggest 4 reasons.

1. It requires time to accumulate and invest savings, more time for the invested savings to be converted into new plants, and a further period of operating the new plants before income reports can reflect a diminishing return. There is evidently a lag in the operation of the mechanism of diminishing returns which may easily amount to more than a year.

2. For concerns which are showing a consistent profit the diminishing returns on capital are reflected in a rising market price for their stocks and bonds. This appreciation of the market value of the principal is a more powerful stimulus to savings than any normal interest return.

3. The rising market values of stocks, bonds, and real estate brings a demand from speculators for the use of savings, at rates which do not reflect diminishing returns.

4. An important fraction of the total savings is used to finance purchases of our products. This use includes nearly all foreign loans, the financing of installment selling, and many other extensions of credit.

These are some of the reasons why diminishing returns do not bring about a prompt and effective regulation of savings to the need for new capital. In consequence strains are built up in the economic system until a break occurs and apparently in 1929 all the above methods of investing savings ceased to attract investors within a period of a few weeks. The flow of savings into these types of investment does not, of course, prove that the same volume of savings could not have been safely absorbed had these savings been invested in more conservative low yield engineering works.

In 3 ways this train of events might have been interrupted.

1. If there had been less savings excessive investment in foreign loans, installment financing, and speculation might have been avoided.

2. If investors had deliberately passed by the greater yield of these forms of investments and used their money to finance self-liquidating projects at a smaller yield there would have been no economic strains and no collapse of our investment machinery.

3. If when the collapse came, every one, including corporations, had immediately changed his saving habits and spent, or given away to be immediately spent, the part of his income which he had been saving, we should have had only a readjustment between different industries and not a semi-paralysis of all industry.

That any of these things should happen as the result of enlightenment or exhortation is too much to expect of human nature. Some form of regulation, probably through shifting the tax load on to the uneconomic forms of investment when these threaten to become excessive, must be developed.

Very truly yours,
F. C. BRECKENRIDGE
(Washington, D. C.)

## What About the Engineer?

*To the Editor:*

In the *Saturday Evening Post* for November 5, 1932, Frank A. Vanderlip, former president of the National City Bank, propounds the question "What about the banks?" and dissertates upon the query with comprehensive scope in his 7,000 word but terse article.

In order to avoid further governmental regulation of our banks, Mr. Vanderlip outlines necessary changes in present practise which the banking fraternity should initiate and adopt. His article culminates in the practical suggestion that the Clearing House Committee, the Federal Reserve Bank, and the New York Stock Exchange jointly prepare a questionnaire that must be answered before any new security issue may be floated in the New York market provided the houses of issue would be amenable to the plan.

At this juncture he suggests a subsequent check by engineers to certify that money obtained for construction purposes had actually been devoted properly to such construction and what commissions or bonuses, if any, were paid. This coming from such high banking authority as F. A.

Vanderlip is a tribute to the engineer for his utility in our society beyond the scope of mere technical production.

We know that we have sometimes seen on bond circulars testimony by engineering firms as to the accuracy of statements concerning plant and property. But, as Mr. Vanderlip implies, they are far too few and these often more of form than of complete fact.

If that practise is to be effective, is to be real, the bank will need to have its own engineer whose work must prove its worth over a period of years. He will need to do more than merely report that so much money has been spent for so much construction of plant. As time goes on methods change, depreciation and obsolescence enter the scene and in the case of many enterprises the more time that elapses the more difficult it becomes to keep a clear distinction between accounted capital and effective capital. While ordinary accounting practise is an accurate procedure, management judgment over a period of years in the handling of a multitude of items in transition from earnings to profit and loss surplus and thus to effective capital, may effect material changes in effective capital and hence earning power. The proper expenditure of a given sum adds that sum to accounted capital but it may add more or less than a given sum to the effective capital, particularly over a period of time. This determination is also proper work for the engineer.

It is the banker's prerogative to make the financial decision as to earning capacity behind any specific bond issue but such decision is arrived at after careful consideration and evaluation of the contributory technical facts furnished by the engineer and by the accountant.

It is to be hoped that the engineering profession will serve to take its part in such a constructive program which will at least help to minimize the bad effects of such a financial debacle as we recently experienced.

Very truly yours,
**Frank C. Czarnecki** (A'15)
(37 West 39th St., New York, N. Y.)

## Method for Fitting a Straight Line to Plotted Points

*To the Editor:*

At times it is desirable to draw a straight line through a number of plotted points and to find the equation of the line which best represents the points. There are various methods employed, such as stretching a string and drawing a line by inspection, the method of averages, and the method of least squares which gives the "best" line.

The method of drawing the line by inspection, and the method of averages, while quite simple and requiring little computation, have the disadvantage of giving inconsistent results; that is, the position of the line is influenced by the judgment of the person drawing it and therefore 2 people might not arrive at the same line from a given set of data.

The method of least squares is admittedly the best method and gives consistent results, but the computations become quite laborious when there is a large number of points.

The following method removes the inconsistencies due to the personal judgment of the computer and involves less labor in computing than the method of least squares. It is believed to be satisfactory for most engineering purposes except where a degree of precision is required which justifies the use of least squares and the lengthier computations involved.

Let $(x_1, y_1), (x_2, y_2), \ldots (x_n, y_n)$ be a series of observed points through which it is desired to draw the straight line of closest fit. Let it also be assumed that the required line will pass through a point whose ordinate is the average of all the observed values of $y$, and whose abscissa is the average of all the observed values of $x$, that is, one point on the line is $(x_a, y_a)$ where $x_a$ equals $\frac{\Sigma x}{n}$ and $y_a$ equals $\frac{\Sigma y}{n}$.

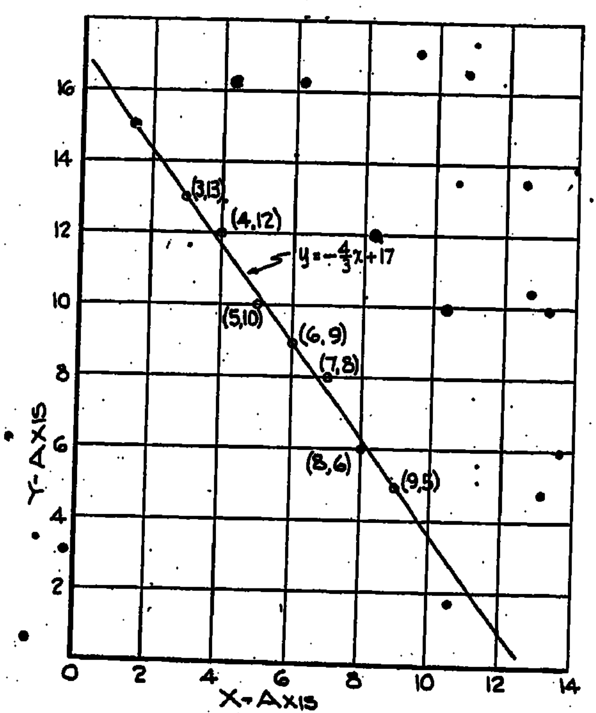

Fig. 1

If the point $(x_a, y_a)$ is now considered as the center of coordinates, the line will have an equation of the form

$$y' = mx'$$

and the coordinates of the points $(x_1, y_1)$, $(x_2, y_2)$, etc., in the original data will be the deviations of the observed points from $(x_a, y_a)$. The straight line will now pass through the new origin, $(x_a, y_a)$, and lie in the first and third, or in the second and fourth, quadrants.

Inasmuch as the line is straight and passes through the new origin, all the points can be placed in one quadrant by giving them the same relative location in that quadrant as they had in the quadrant from which they were removed. This is the same as considering all the deviations as having the same sign. By averaging all the absolute values of the $x$ deviations and all the values of the $y$ deviations, the point $(x_b, y_b)$ is obtained, where $x_b = \frac{\Sigma|d_x|}{n}$ and $y_b = \frac{\Sigma|d_y|}{n}$; $\Sigma|d_x|$ and $\Sigma|d_y|$ being the sum of the absolute values of $(x_1 - x_a)$, $(x_2 - x_a)$, etc., and $(y_1 - y_a)$, $(y_2 - y_a)$, etc., respectively.

The equation of the line passing through the origin $(x_a, y_a)$ and the point $(x_b, y_b)$ is

$$y' = \frac{y_b}{x_b} x'$$

$$= \frac{\frac{\Sigma|d_y|}{n}}{\frac{\Sigma|d_x|}{n}} x' = \frac{\Sigma|d_y|}{\Sigma|d_x|} x'$$

where $\frac{\Sigma|d_y|}{\Sigma|d_x|}$ is the slope.

If the line is now referred to the point $(0, 0)$ as the origin instead of $(x_a, y_a)$, its equation becomes

$$y - y_a = \frac{\Sigma|d_y|}{\Sigma|d_x|}(x - x_a)$$

$$y = \frac{\Sigma|d_y|}{\Sigma|d_x|} x + \frac{\Sigma y}{n} - \frac{\Sigma|d_y|}{\Sigma|d_x|} \frac{\Sigma x}{n}$$

the slope being $\frac{\Sigma|d_y|}{\Sigma|d_x|}$ and the $y$ intercept being $\frac{\Sigma y}{n} - \frac{\Sigma|d_y|}{\Sigma|d_x|} \frac{\Sigma x}{n}$.

The sign of $\frac{\Sigma|d_y|}{\Sigma|d_x|}$ is determined by noting the signs of the deviations. If it is found that the $x$ deviations and their corresponding $y$ deviations have like signs the slope of the line is positive and $\frac{\Sigma|d_y|}{\Sigma|d_x|}$ is plus; if the signs are unlike the slope of the line is negative and the minus sign is used with $\frac{\Sigma|d_y|}{\Sigma|d_x|}$.

The following example, illustrated in Fig. 1, is worked out in detail to show the method.

| $x$ | $x_a$ | $d_x$ |
|---|---|---|
| 3 | − 6 | −3 |
| 4 | − 6 | −2 |
| 5 | − 6 | −1 |
| 6 | − 6 | 0 |
| 7 | − 6 | +1 |
| 8 | − 6 | +2 |
| 9 | − 6 | +3 |
| $\Sigma x = 42$ | | $\Sigma\|d_x\| = 12$ |

| $y$ | $y_a$ | $d_y$ |
|---|---|---|
| 13 | − 9 | +4 |
| 12 | − 9 | +3 |
| 10 | − 9 | +1 |
| 9 | − 9 | 0 |
| 8 | − 9 | −1 |
| 6 | − 9 | −3 |
| 5 | − 9 | −4 |
| $\Sigma y = 63$ | | $\Sigma\|d_y\| = 16$ |

$$x_a = \frac{42}{7} = 6 \qquad y_a = \frac{63}{7} = 9$$

The slope of the line is

$$-\frac{16}{12} = -\frac{4}{3} = -1.333$$

It is given the negative sign because the corresponding values of $d_x$ and $d_y$ are unlike. The $y$ intercept is

$$9 - \left(-\frac{4}{3}\right) 6 = 9 + 8 = 17.$$

and the required equation is

$$y = -\frac{4}{3}x + 17$$

The least squares line has been worked out and is

$$y = -1.35x + 17.1,$$

showing that the method described agrees quite closely with the least squares "best" line and is satisfactory for a great many applications.

Very truly yours,
**Hector B. Samson** (A'27)

Dunmore, Pa.)

## Graphical Determination of the Symmetrical Components in a 3-Phase Unbalanced System

*To the Editor:*

An unbalanced 3-phase system may be resolved into 3 sets of symmetrical components which are: 2 balanced 3-phase systems of opposite rotation and a uniphase component. When great accuracy is needed, these components are analytically determined with 3 equations, following a method developed by C. L. Fortescue.

As far as I know, the graphical solutions that have been suggested make use of a

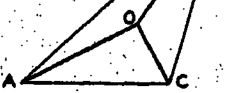

Fig. 1

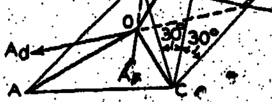

Fig. 2

ferent geometrical construction to deter- ne each one of the components. In this ter, I would suggest a general solution it can be performed on a single diagram. We shall first consider the case when there no residual component; afterward it l be shown that the solution equally plies when the sum of the 3 vectors is : zero.

### RESIDUAL COMPONENT

Let us take the 3 unbalanced vectors ., $OB$, and $OC$ whose sum is zero (Fig. 1). Join the points $ABC$ of the vectors by aight lines, thus making a triangle g. 1).

Through the middle point of the side ', draw a line $XY$ perpendicular to $BC$ g. 2). From the corner $C$, draw 2 aight lines, respectively, making a 30° gle on each side of $BC$; these 2 lines ersect the perpendicular $XY$ at $A'_r$ and ι. Joining $A'_r$ and $A'_d$ to the neutral we get the lines $OA'_r$ and $OA'_d$.

$)A'_r$ is equal in magnitude to the reverse ıse component of $OA$; this line $OA'_r$ ıuld be prolonged past $O$ to obtain the ıt vectorial position, which is 180° m $OA'_r$, to a point $A_r$ equally distant n $O$ as $A'_r$.

Similarly $OA'_d$ is equal to the direct ıse component and 180° out of phase;

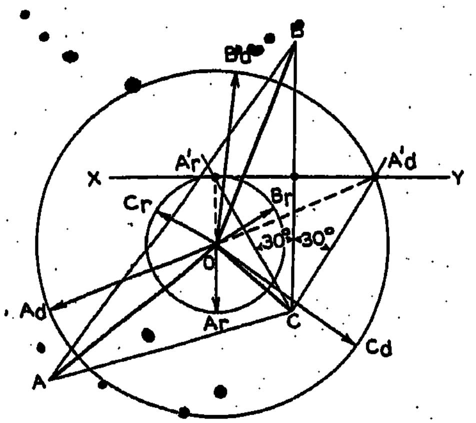

Fig. 3

long this vector through $O$ by an equal gth in the opposite direction.

Now that we know the components of in each symmetrical system, it is easy find out the components of the other ıses because they are symmetrical and ° apart from each other. The solution nade easier if we draw 2 circles with $O$ center and $OA'_r$ and $OA'_d$ as radii g. 3).

Any side of the triangle may be used to ermine the initial components, the side en always giving the components of the osite phase: *e. g.*, side $BC$ giving components of $OA$, side $AB$ giving components $)C$ and side $CA$ giving components of $OB$.

### NERAL SOLUTION

The method usually followed when there ı uniphase component is to add the 3 tors and find out their sum; the sum is al in magnitude and direction, to 3 es the uniphase component. After- 'd this component is subtracted from h vector and with these new vectors we ıe back to the problem as explained ve.

However, it can be noted that when the phase component has been subtracted n each vector (Fig. 4), the new enclosing ngle $A'B'C'$ is equal to the original ngle $ABC$.

Also the distance between the origin of vectors $O$ and the center of gravity $O'$ the triangle $ABC$ (Fig. 5), is equal in magnitude and direction to the uniphase component.

From the above considerations we can draw 3 conclusions:

1. **When there is a residual component the enclosing triangle can still be used for the solution.**
2. **Joining the extremities $A$, $B$, and $C$ of the vectors to the triangle center of gravity is equivalent to subtracting the uniphase component from each vector.**
3. **The triangle center of gravity, and not the neutral point, should be used for finding the symmetrical components. (When there is no uniphase component, the neutral point and the center of gravity coincide.)**

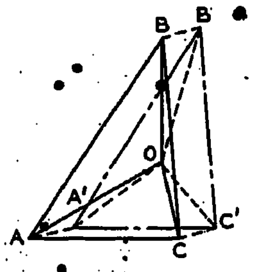

Fig. 4

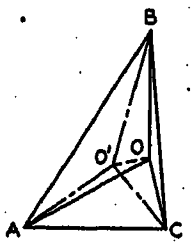

Fig. 5

### PROCEDURE

The following procedure is suggested for a general graphical solution (Fig. 6):

1. **Draw a triangle around the 3 unbalanced vectors $OA$, $OB$, and $OC$ as previously described.**
2. **Locate the triangle center of gravity, $O'$ (in a triangle, the center of gravity is at the intersection of the 3 lines joining each corner to the middle of the opposite side; it is always located at $^1/_3$ of the height).**
3. **Erect a perpendicular $XY$ to the side $BC$ through its middle point.**
4. **From the corner $B$, draw 2 lines, respectively, making a 30° angle on each side of $BC$; these 2 lines intersect the perpendicular $XY$ at $A'_d$ and $A'_r$.**
5. **Draw 3 circles with $O'$ (center of gravity) as common center and, respectively, passing through the points $O$, $A'_d$, and $A'_r$.**
6. **Prolong the lines $O'O$, $O'A'_d$, and $O'A'_r$ through $O'$ to the opposite side of their respective circles.**

We now have the 3 components for the vector $OA$. The direct and reverse sequence components for the other vectors $OB$ and $OC$ are 120° apart from the components of $OA$; the uniphase component is the same for the 3 vectors.

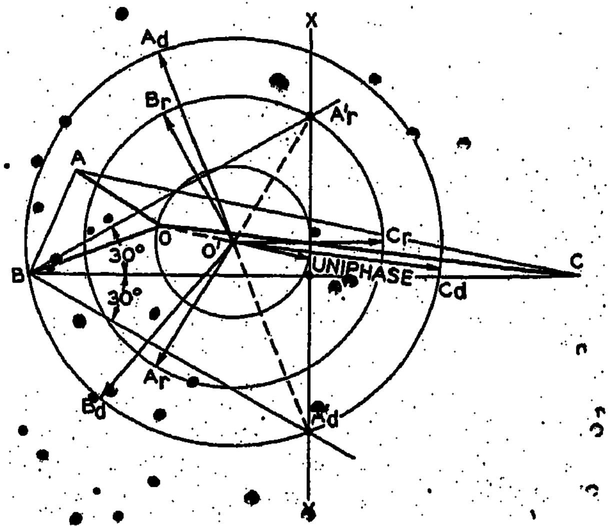

Fig. 6

Apart from its completeness, this method would be very convenient for a quick estimate of the unbalance factor.

Very truly yours,
R. LAPLANTE (A'32)
(Shawinigan Water & Power Co.,
Shawinigan Falls, Quebec, Can.)

## Young Engineers Must Plan for the Future

*To the Editor:*

The "Letter to the Editor" from Dr. Valdimir Karapetoff published in the September 1932 issue of ELECTRICAL ENGINEERING, p. 669, proposes a fundamental change in educational methods in the United States that would be of great value to the engineering profession as a whole, were it put into practise generally. Briefly, it consists of training the engineering student along such lines that in this rapidly advancing profession he will be capable of doing modern engineering work soon after graduation, without the necessity of first going through various training and test jobs to find out what the engineering profession has been doing in the 10 years since his textbooks were written, and what it is going to do in the next 10 years. The chief advantage of such an educational method lies in the hope that an engineer trained in college to look beyond present achievements may perchance carry the habit with him into professional life.

Two years ago I listened to Dr. Karapetoff talk to a small group of prominent physicists and 2 engineers about the need for applied scientists and theoretical engineers to act as intermediaries between mathematical physicists and practising engineers. As a very pertinent example of a problem badly in need of such treatment, Dr. Karapetoff mentioned very briefly the polymerization of insulating materials in high voltage cables. In the discussion that followed, the subject of Dr. Karapetoff's talk and the purpose of his visit were completely forgotten in the advancing of hair-trigger theories about polymerization; the 2 engineers were visitors and so listened and went away without learning how to better effect an interchange of knowledge and experience with their physicist acquaintances.

It is rather apparent that any constructive action in this direction must start from the engineers' side of the fence; later perhaps, the theoretical physicists may change their attitude sufficiently to welcome with more open arms the advances of men who are motivated solely by a sincere wish to further scientific knowledge and technical achievement. For the present it seems that with a few notable exceptions, physicists do not care to extend their activities toward engineering fields, and indeed do not care to offer instruction to those who seriously contemplate applied physics and theoretical engineering.

In the research laboratories of our large electrical industries there may be found the applied scientists and theoretical engineers necessary to the rapid advance of industrial art. The small organizations are indeed fortunate to have at their call the services of such individuals. The training facilities of these research laboratories are much too restricted to supply the needs of the engineering profession in the future for scientifically trained men, and it remains for the colleges and universities to take over a large part of the burden.

The 4-year college course has in the past been the greatest stumbling block to engineering training. To get something more than a trade school education in 4 years of college and not at the same time neglect the technical courses, is at present well-nigh impossible. Formerly a student could neglect to a great extent the technical side of his college education for the cultural side, taking up the technical features as needed after graduation. Now such a very great deal is expected of the engineering graduate that that course is no longer possible; and indeed, after a rigorous 4-year college course leading to a degree in engineering, most graduates still need much further engineering study, not to mention cultural studies. Some get advanced work in post-graduate courses, others in apprentice jobs, and many more neglect it entirely and drift to other fields of endeavor.

Perhaps the solution is a 5 or 6-year course, leading to a master of engineering degree, with the last 2 years patterned more after the English plan of independent work and personal supervision by a faculty member, but there again rises the necessity of many promising students to abandon study after 4 years to enter wage-earning fields. Some solution can and should be worked out; for without more time, it is impossible without neglecting other necessities, to do more than mention the things Dr. Karapetoff speaks of so earnestly.

Very truly yours,
**Frank W. Godsby** (A'30)
(Development Engineer, The Safety Car Heating and Lighting Co., New Haven, Conn.)

## Reactive Volt-Amperes

*To the Editor:*

The lines in the usual diagrams illustrating power factor correction are vectors of volts and amperes although they may be labelled (convenience excusing such labelling) kilowatts and reactive volt-amperes.

A-c volt-amperes, whether watt or wattless, are not vector quantities, and they cannot be represented by vectors. It is only by a confusion of ideas that the operator $j$ is applied to watts or to volt-amperes.

In the useful pamphlets (GET-191A and GEA-1508), recently published by the General Electric Company, the current vectors labelled "leading reactive kva" are shown lagging instead of leading, and lagging vectors are shown leading. Also we find the queerly muddled sentence: "This 'wattless' current or rkva may lag behind the voltage wave."

I suggest that the common practise of using the mongrel term "reactive power" be given up in favor of "reactive volt-amperes"; that the practise be adopted of stating plainly that the vectors labelled power and volt-amperes in power factor correction diagrams are vectors of volts or of amperes, as the case may be, and that, in such diagrams the convention common to other vector diagrams be followed of measuring angles of lead counter-clockwise.

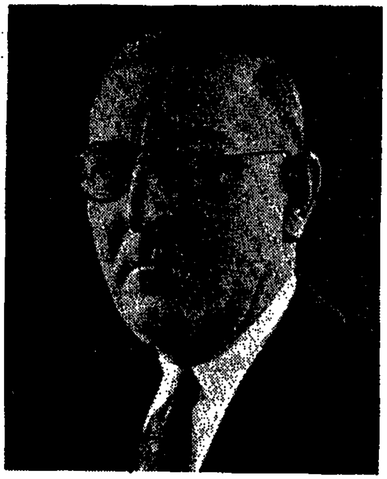
Very truly yours,
**F. M. Denton** (A'08, F'28)
(Head of Electrical Engg. Dept., University of New Mexico, Albuquerque)

## Karl S. Wagner Sought by Legation

Institute headquarters has been advised by the Roumanian Legation at Washington, D. C., that the "legation has very important information of a personal character and interest" for one Karl S. Wagner, whom the legation describes as an American engineer having traveled in Russia in 1913 in the employ of a New York company. Some time later he is reported to have moved to Michigan.

Members knowing the whereabouts of Engineer Wagner may do him a personal favor of some importance by conveying this information to him, that he may act accordingly.

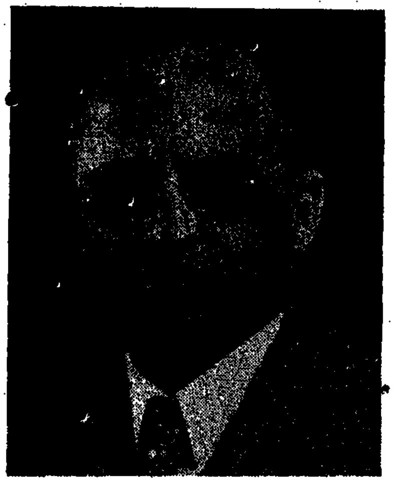
# Personal



W. T. BLACKWELL

**W. T. Blackwell** (A'22) general lighting representative of the Public Service Electric and Gas Company, Newark, N. J., has received reelection for the current year to the chairmanship of the Institute's technical committee on the production and application of light. Mr. Blackwell's early education consisted of private tutelage and preparatory school. In 1897 at the age of 18 he entered the construction department of the New York Telephone Company, New York, N. Y., remaining there until in 1902 when he became engineer in charge of street construction for the East River Gas Company, Long Island City. Mr. Blackwell has been associated with the lighting industry since 1905; in that year he was appointed assistant to the chief engineer of light and power, department of water supply, gas, and electricity, New York City, remaining in this position until 1915, when he was made illuminating engineer for the Benjamin Electric Manufacturing Company of New York City. After 2 years of service with this company, he was commercial and illuminating engineer for the Westinghouse Lamp Company, New York, for 4 years, and manager of the interior illumination department of the Westinghouse Electric and Manufacturing Company for one year. During the past 10 years he has been general lighting representative of the Public Service Electric and Gas Company. He has contributed many technical papers on illumination. Among the societies of which he is a member are: Illuminating Engineering Society, National Electric Light Association, National Safety Council, The American Society of Municipal Engineers, Newark Safety Council, and Essex Electrical League. Mr. Blackwell has served on the Institute's committee on the production and application of light since 1924, and since 1931 has been its chairman, thus automatically becoming a member of the Institute's technical program committee.

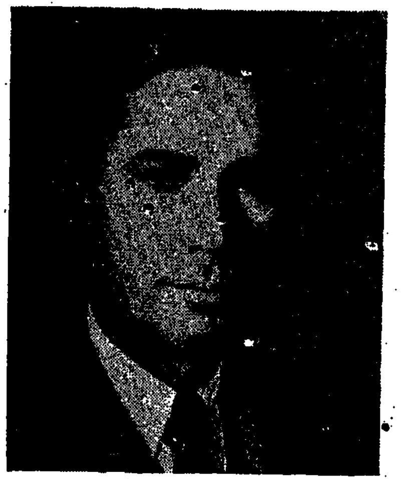
**W. R. Whitney** (A'01) organizer and for 32 years director of the research laboratory of the General Electric Company, Schenectady, N. Y., retired from that position owing to poor health on November 1, 1932. He was succeeded by Dr. **W. D. Coolidge** (A'10) formerly senior associate director of the laboratory. Doctor Whitney continues as vice-president in general charge of research. The research laboratory was established in 1900, and in that year Doctor Whitney came from Massachusetts Institute of Technology where he was an instructor, to be in charge of the research work. At that time the laboratory was in an old barn which was used by the late Dr. C. P. Steinmetz as a private laboratory. A few months later a small building at the General Electric works was secured. The expansion of the laboratory followed the development by Doctor Whitney of a new type of incandescent electric lamp, and since 1903 the laboratory has grown rapidly. By 1920 the laboratory's staff had grown to more than 300 persons, about half of whom were trained scientists; the value of this laboratory has long been recognized by the electrical industry. Among the many honors which Doctor Whitney has received was the Franklin Medal of the Franklin Institute on May 20, 1931. This award is made to "workers in physical science or technology without regard to country, whose efforts in the opinion of the administering committee on science and arts, have done most to advance a knowledge of physical science or its application." Doctor Whitney was assistant and later non-resident professor of theoretical chemistry at Massachusetts Institute of Technology, and is a member of the corporation of this institution.



W. R. WHITNEY

**A. LeRoy Taylor** (M'28), head of the department of electrical engineering, University of Utah, Salt Lake City, has been appointed chairman of the technical program committee for the 1933 Pacific Coast Convention of the Institute to be held in Salt Lake City during the summer of 1933. He was born at Logan, Utah, in 1887. He received the degree of B.S. in E.E. in 1907 from the University of Utah and the degree of master of science in engineering in 1918 from the University of Michigan, specializing in mechanical engineering. During 1910 and 1911 he was in the testing department and the standardizing laboratory of the General Electric Company at Schenectady, N. Y., thereafter being instructor in electrical engineering at the University of Utah for a one-year period. Following this he spent 2 years in business, returning to the University of Utah in 1914 and remaining there since that time. He has been assistant and later associate professor of mechanical engineering at this institution, and since 1928 has been head of the department of electrical engineering. Professor Taylor has served the Utah Section as a member of its executive committee 1930–31, secretary 1931–32, and chairman 1932–33. He has also been chairman of the Utah Section of The American Society of Mechanical Engineers and has been secretary of the Engineering Council of Utah.

**D. E. Renshaw** (M'29) in charge of the petroleum mining section of the general engineering department, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., recently received reappointment as chairman of the Institute's technical committee on applications to mining work. Mr. Renshaw was born in Hennessey, Okla., in 1891. After completing his local high school course, he attended the University of Oklahoma, at Norman, from which he was graduated in 1914 with the degree of B.S. in E.E. Between 1912 and 1914 he was electrician at this university. Upon graduation he was on the student course of the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., for a year. From 1915 to 1917, he was in the railway engineering department of that company. He then left to join the United States Navy, which he served for 2 years. In 1920 he returned to Westinghouse and remained in the railway equipment engineering department until 1923, after which for 2 years he represented the Westinghouse company in France and Spain, supervising erection of the car and locomotive equipment on the Paris-Orleans Railway and the Spanish Northern Railway. In 1925 he returned to the railway equipment engineering department of the Westinghouse company. Since 1928 he has been section engineer in charge of the mining section, general engineering department and for the past year has had charge of the petroleum section, also. Mr. Renshaw has served the Institute's committee on applications to mining work for the past 3 years and since 1931 has been its chairman. His other A.I.E.E. committee work has included membership on the technical program and standards committees since 1931.



D. E. RENSHAW

**W. D. Coolidge** (A'10) formerly senior associate director of the research laboratory of the General Electric Company, Schenectady, N. Y., was appointed on November 1, 1932, as director of this laboratory to succeed Dr. W. R. **Whitney** (A'01) who retired on that date. Doctor Coolidge is a native of Hudson, Mass. He studied at the Massachusetts Institute of Technology and the University of Leipzig. Since 1905 he has been active in the research work of the General Electric Company, becoming assistant director of the laboratory in 1908 and associate director in 1928. A personal item mentioning some of the achievements of Doctor Coolidge was given in Electrical Engineering for March 1932, p. 210–11, in connection with his winning the Washington award for 1932.

W. D. COOLIDGE

**J. H. Hamilton** (A'28), associate professor of electrical engineering at the University of Utah, Salt Lake City, has been appointed chairman of the student activities committee for the 1933 Pacific Coast Convention to be held in Salt Lake City. He was born at Los Angeles, Calif., in 1904 and graduated from the California Institute of Technology at Pasadena. After engaging as technical assistant on lightning research for the Union Oil Company of California and the General Petroleum Corporation, during 1926 and 1927, he became technical assistant for Kobe, Inc., Los Angeles, Calif., being engaged in the design of a magnetically controlled heat treating furnace. He was then for a while teaching fellow at the California Institute of Technology, and secured his doctor's degree from this institution in 1928. He is now Student Branch counselor at the University of Utah and an ex-officio member of the Institute's committee on student branches. For the year 1931–32 he was chairman of the North West districts committee on Student activities and a member of the excutive committee for this district. He is now a member of the executive committee of the Utah Section.

**Eugene Caldwell** (A'26), formerly chief mechanical engineer for the Central Public Service Corporation, Chicago, Ill., now is general manager of the Wrought Washer Manufacturing Company. Mr. Caldwell was editor-in-chief of *Industrial Power* for several years. He graduated from Ohio State University, Columbus, in 1922, and later took a special course at Massachusetts Institute of Technology, Cambridge, Mass. He is a member of the executive committee of the Institute's Chicago Section and chairman of the publicity committee of this Section. He is a member of The American Society of Mechanical Engineers, the publication committee of the Society of Industrial Engineers, and various committees of the National Electric Light Association. He is coauthor of a new textbook "American Industries," being used by New York University, and has contributed many articles to the technical press.

**C. E. Stephens** (M'22) formerly commercial vice-president and northeastern district manager of the Westinghouse Electric & Manufacturing Company, at New York, N. Y., was named vice-president. Mr. Stephens has been connected with the Westinghouse company since 1900, and with the New York office since 1917, having been appointed manager of the supply department in that year and later being made manager of the central station division, and in 1925 manager of the company's New York office. In 1930 he was elected commercial vice-president. He was at one time vice-president of the Illuminating Engineering Society. He has been active for many years in the A.I.E.E. and at present is a director of the Institute, chairman of the finance committee, and a member of several other of the Institute's committees.

**C. H. Douglas** (M'18) for some 12 years a St. Louis engineering-sales representative of various electrical manufacturing concerns now has become sales manager of the Industrial Products Sales Corporation, St. Louis. Mr. Douglas is a native of Walnut Ridge, Ark. (Feb. 5, 1886) graduated from the University of Arkansas in 1911 with degree of Bachelor of Science in electrical engineering, immediately after which he became associated with the Union Electric Light & Power Company of St. Louis; he became distribution engineer of that company in 1916. In June 1915 the University of Arkansas awarded him the degree of Electrical Engineer in recognition of advanced work completed.

**H. H. Barnes, Jr.** (A'00, M'04, F'13), vice-president of the General Electric Company, New York, N. Y., has been appointed chairman of the electrical industries and general machinery group of the Emergency Unemployment Relief Committee of

New York City, engaged in raising funds for unemployment relief during the winter 1932–3. This division, which is organizing 100 major trade groups through which funds will be solicited from employers, employees and employees' associations, last year raised more than $10,000,000 to finance "made" work and direct relief for the jobless. Last year Mr. Barnes headed the activities of the electrical industries for this committee.

**C. M. Lear** (M'31) has been appointed to serve as an instructor in the physics department of the University of Florida, Gainesville. Mr. Lear is a native of Charlottesville, Va. (Nov. 21, 1907); in 1930 he graduated from the University of North Carolina with the degree of Bachelor of Science in electrical engineering. For advance work he expects to receive in June 1933 from this same university his Master's degree in physics. He spent 2 years as a student engineer in the General Electric test department, Schenectady, N. Y. (1928–9 and 1930–1).

**F. H. Knapp** (A'28), who was assistant field engineer, area of the New York Telephone Company, for the Bell Telephone Laboratories, Inc., New York, N. Y., and later was located at St. Louis, Mo., engaged on work for the Southwestern Bell Telephone Company, now has returned to the Bell Telephone Laboratories, Inc., at New York, as field engineer, area of the Southwestern Bell Telephone Company. Mr. Knapp secured his E.E. degree from Rensselaer Polytechnic Institute in 1926.

**F. W. Smith** (A'05, M'12), who early this year became president of the New York Edison Company and the United Electric Light and Power Company, has been elected a member of the board of trustees of the Consolidated Gas Company, New York, N. Y. A personal item, outlining Mr. Smith's career, was given in ELECTRICAL ENGINEERING for March 1932, p. 210.

**E. W. Feller** (A'27) was recently transferred from the operating department of the Pennsylvania Water and Power Company at Holtwood, Pa., to the operating department of the Safe Harbor Water Power Corporation, Safe Harbor, Pa. Mr. Feller had been with the Pennsylvania Water and Power Company since 1924.

**G. R. Anderson** (A'22, M'29) in charge of the induction motor section of Fairbanks Morse & Company, Beloit, Wis., during the past year, recently was appointed chief engineer of the electrical division of the company.

**C. J. Huber** (A'13) formerly manager of the product engineering division of Cheny Brothers, South Manchester, Conn., is now engaged on special work with the U.S. Testing Company, Hoboken, N. J.

**H. R. Kelly** (A'28), formerly statistician in the quality department of RCA-Victor, Inc., Camden, N. J., is now administration head of the engineering department of this company.

**W. H. Pollard** (A'24) formerly an electrical engineer at the Indianapolis, Ind., works of Fairbanks Morse & Company, now is located in the Beloit, Wis., works of this company in the capacity of designing engineer.

## Obituary

**R. F. Schuchardt** (A'03, M'09, F'12, and past-president) chief electrical engineer of the Commonwealth Edison Company, Chicago, Ill., died in Boston, Mass., on October 25, 1932. Mr. Schuchardt had long been considered one of the foremost engineers of the United States. He was born in Milwaukee, Wis., in 1875, and in 1897 graduated from the electrical engineering course of the University of Wisconsin. Following graduation he spent a short period with the Janesville (Wis.) Electric Light and Power Company, later in that year he joined the staff of Meysenburg and Badt, Chicago, Ill., as engineering salesman. In July 1898, he entered the employ of the Chicago Edison Company (later the Commonwealth Electric Company and Commonwealth Edison Company) remaining with this organization until the time of his death. After a few weeks, first as substation operator and then in charge of the company's exhibit at the Trans-Mississippi Exposition, Omaha, Neb., he spent one year in the statistical department of the company. Between 1899 and 1906 he was in the testing department, through all stages from assistant to acting head. In 1906 he became engineer of electrical construction, having charge of this work for all stations and substations. In 1909 he was appointed electrical engineer of the company, and from that date to 1932 he has been intimately connected with the development of the company. He has made many contributions to technical literature since the presentation in 1897 of his first paper "Electricity Meters of Today" which attracted considerable attention. Mr. Schuchardt has long been active in the A.I.E.E., having served on many committees including the educational, power generation, power transmission and distribution, protective devices, standards, meetings and papers, executive, electrical machinery, law, Edison Medal, and public policy committees, as well as on the committee on code of principles of professional conduct. He has served as the Institute's representative on the U.S. national committee of the International Electrotechnical Commission, the administrative board of the American Engineering Council, the board of award of the John Fritz Medal, the Coffin fellowship and research fund committee, and on the joint committee of the engineering societies on participation of the engineering profession in the Century of Progress Exposition to be held in Chicago in 1933. From 1928 to 1929, Mr. Schuchardt was president of the Institute. He also was chairman of the Chicago Section of the Illuminating Engineering Society, chairman of the technical national section of the National Electric Light Association, member of the Western Society of Engineers, the Society for the Promotion of Engineering Education, and the Institution of Electrical Engineers of Great Britain. He has been chairman of the public affairs committee of the American Engineering Council, and in 1929 was a delegate to the World Engineering Congress in Japan.

**Edwin Nash Sanderson** (A'94, M'13, and Life Member) member of the firm of Sanderson and Porter, and president of the Federal Light and Traction Company, New York, N. Y., and of its 30 subsidiaries throughout the country, died November 9, 1932. He was born in Brooklyn, N. Y., in 1862. He attended Brooklyn Polytechnic Institute for 4 years and then attended Rensselaer Polytechnic Institute an additional 4 years, graduating with the degree of civil engineer in 1886. In 1887 he received the degree of M.E. from Cornell University. Between 1887 and 1896 he was with the Westinghouse Electric and Manufacturing Company, being an engineer at East Pittsburgh for one year, then engineer and salesman in New York for 5 years, manager of the New England district at Boston, Mass., for one year, and assistant to the general manager at East Pittsburgh for 2 years. In 1896 he resigned from the Westinghouse company; in this year the firm of Sanderson and Porter was formed and has since then remained active in the construction, management, and operation of electric railway, light and power properties. In 1910 his public utility holdings were incorporated into the Federal Light and Traction Company. Most of the major construction work of this company was performed by the firm of Sanderson and Porter, of which H. Hobart Porter (A'96, M'12, and Life Member), president of the American Water Works and Electric Company, Inc., New York, is the other senior member. One of Mr. Sanderson's major accomplishments was the construction in 1907 of one of the first hydroelectric projects in the Sierras, for the operation of the street railways of San Francisco, Calif. He was a member of The American Society of Mechanical Engineers, the Rensselaer Society of Engineers, the Cornell Society of Engineers, and Sigma Xi and Zeta Psi fraternities. He was a life member of the Board of Trustees of Cornell University. In 1925 Colgate University conferred upon him the honorary degree of Doctor of Law. Among his clubs were the University, City Midday, St. Bernard Fish and Game, Columbia Yacht, Town and Gown, and Cornell clubs, all of New York, the Union Club of St. John, N. B., and the Orchard Lake, Adirondack Mountain, and Westchester Country Clubs.

**D. H. Braymer** (M'15) head of the D. H. Braymer Equipment Company, Omaha, Neb., died October 29, 1932. He was born in 1883 at Hebron, N. Y. He secured his A.B. degree in 1906 from Cornell University, and his M.E. in E.E.

degree in 1908 from the same institution, having completed both mechanical and electrical engineering courses. During the summer of 1906 he was draftsman for the Morse Chain Company, Ithaca, N. Y., and during the summer of 1907 was electrical tester for the Electrical Testing Laboratories, New York, N. Y. He also held this latter position for a short time in 1908, becoming an engineer in the service and maintenance department of the New York plant of the Western Electric Company in that year. From 1909 to 1910 he was electrical engineer visiting and reporting on the Western Electric Company's power plant and telephone equipment in the capacity of publicity engineer. From 1910 to 1915 he was at Atlanta, Ga., on the staff of the *Southern Electrician* and succeeding magazines, being editor the latter part of this period. In 1915 he joined the McGraw-Hill Publishing Company as associate editor of the *Electrical World*, later becoming engineering editor, and then managing editor and coeditor. When the *Electrical Review* was purchased by the McGraw-Hill Company, Mr. Braymer was placed in charge of both the publishing and editorial policies of this magazine, which started under the name of the *Industrial Engineer*. In 1925, Mr. Braymer relinquished his editorial duties to organize the company which bears his name, specializing in consulting and sales work associated with power applications in industrial plants, large buildings, and power plants. He was at one time chairman of the Nebraska Section.

JOHN L. SWITZER (Enrolled Student) who recently received the Kruesi Improvement Prize awarded to senior students at the University of Tennessee, Knoxville, died October 1932. Mr. Switzer had been a student at the University of Tennessee, graduating from the electrical engineering course in June 1932 and had enrolled as a full-time graduate student for the coming year. The Kruesi prize, which he had just received, was established by Paul J. Kruesi of Chattanooga, for the benefit of engineering students at the University of Tennessee and is awarded each year to students of the graduating class who have been 3 years in attendance at the University of Tennessee. The award is made to that student of the senior class who by vote of the faculty of the college of engineering has made the most progress while a student, taking into consideration his preparedness, early opportunities, effort expended as a student, financial difficulties, ability, and activities outside of the curriculum. One prize is given in each of 4 engineering courses and covers the initiation fee and first year's dues in one of the following 4 engineering societies: American Chemical Society, The American Society of Mechanical Engineers, American Institute of Electrical Engineers and American Society of Civil Engineers. Mr. Switzer had been awarded membership in the Institute.

FRANK T. MORRISSEY (A'16) who for the past few years has been president of F. T. Morrissey & Company, Inc., Dallas, Texas, died September 10, 1932. Mr. Morrissey was born at Waltham, Mass., in 1885, and in 1900 was apprentice to I. A. Nourse, electrical engineer, Westboro, Mass., receiving special instruction in power plant design and maintenance. After serving between 1903 and 1906 in the U.S. Army, he was assistant to the chief engineer of the Saxony Worsted Mills, Newton, Mass., for 2 years. Between 1908 and 1910 he was district superintendent of the Eastern Michigan Edison Company at Wayne, Mich., and at Ann Arbor, Mich., thereafter being in the engineering department of the Kansas City Electric Light Company, Kansas City, Mo., for one year. He was at one time president and general manager of the Warren Light and Power Company, Inc., and later general superintendent of the Plymouth Electric Light and Power Company, Plymouth, Ind. This was followed by other similar engagements. His own company, which he organized a few years ago, was engaged as selling representatives and engineers for manufacturers' equipment.

IRA BURNARD MATTHEWS (A'17) superintendent of the transformer department of the Toledo Edison Company, Toledo, Ohio, died suddenly at his work October 25, 1932. Mr. Matthews was born in Defiance, Ohio, in 1877. In his youth he came to Toledo where he obtained his early education, later attending Toledo University. He remained in this city the rest of his life, being employed in 1894 by the Western Union Telegraph Company, in 1896 by the Harrison Telephone Company, in 1897 by the Buckeye Pipe Line Company, in 1901 by the Toledo Western Electric Railway, in 1903 by the Pennsylvania Railroad Company, and since 1905 by the Toledo Railways and Light Company, now the Toledo Edison Company. Mr. Matthews served as foreman in the line department of this company until the organization of the transformer department, when he was made superintendent of this department. He had a wide experience in the general construction of telephone, telegraph, and low and high voltage electrical equipment.

LEONARD G. VAN NESS (A'04), consulting engineer of Memphis, Tenn., and Lodi, Wis., died on September 24, 1932. He was born at Lodi in 1869 and graduated from the University of Wisconsin with the degree of B.S. in E.E. in 1896. He was then employed in the machine shop of the Elgin National Watch Factory at Elgin, Ill., for one year and was then engaged in power line construction for a year. Between 1898 and 1902 he was electrical engineer with Emerson-McMillan Company engaged in central station work for companies in a number of different cities. In 1902 he became general manager of the Lincoln Gas and Electric Light Company at Lincoln, Nebraska. Later he was an official of the Memphis (Tenn.) Gas and Electric Company and remained active in public utility construction during his career. He had a wide experience in construction and rehabilitation of gas and electric properties and was considered an expert in analyzing the costs of operation and in conducting rate investigations.

WALTER L. WOODMANSEE (A'23) chief electrician of the American Steel and Wire Company, South Works, Worcester, Mass., died recently as a result of severe burns received while making some electrical connections at the plant. Mr. Woodmansee was born in 1875 in Noank, Conn. Between 1896 and 1898, he was engaged in the construction and testing of electrical motors and generators at the Eddy Electrical Company, Windsor, Conn., and between 1898 and 1902 was installing and repairing motors and generators for the W. C. McIntire Company, Philadelphia, Pa. For 2 years following 1902, he undertook electrochemical experimental work for Rogers and Hite, Conshohocken, Pa., after which he spent 2 years rebuilding electrical machinery for Yearsley and Levene, Philadelphia, Pa. From 1906 until the time of his death, he held the position of chief electrician at the plant of the American Steel and Wire Company.

WILLIAM ALEXANDER BARRETT (A'07) died on May [illegible], 1932, according to word recently received at the Institute headquarters. He was born at Wadesboro, N. C., in 1881, and was a graduate of the North Carolina Agricultural and Mechanical College in the electrical engineering course. Following graduation he was employed by the Union Electric Company of St. Louis, Mo., as meter inspector for one year, and later held a similar position with the Missoula Light and Water Company at Missoula, Mont. More recently, Mr. Barrett was electrician at the Puget Sound Navy Yard, Bremerton, Wash.

# Addresses Wanted

A list of members whose mail has been returned by the postal authorities is given below, with the address as it now appears on the Institute records. Any member knowing of corrections to these addresses will kindly communicate them at once to the office of the secretary at 33 West 39th St., New York, N. Y.

Anderson, F. C., 741 Oak Ave., Westfield, N. J.
Bohner, C. W., 620—22nd Terrace, Miami, Fla.
Brock, Geo., 1117 N. 15th St., Milwaukee, Wis.
Florez-Estrada, Jose, Avenida De La Paz 60, Reparto Alture-Rio Almendares, Marianao, Havana, Cuba.
Heiser, Edwin S., 413 Federal Bldg., St. Paul, Minn.
Jefferson, H. F., 633 Portola Ave., Glendale, Calif.
Katz, Henry, 2714 Wallace Ave., New York, N. Y.
Keller, Dr. Max Leo, Kornweg 8, Aarau, Switzerland.
Kirby, F. M., 25 E. 40th St., New York, N. Y.
McShane, Joe B., 810 Western Natl. Bldg., San Antonio, Texas.
Newman, Rexford C., 100 High St., St. Clairsville, Ohio.
Nimetz, John B., 3442 Sacramento St., San Francisco, Calif.
Olsen, V., P. O. Box 404, Shanghai, China.
Peterson, Alex., Central West Pub. Serv. Co., Omaha, Nebr.
Schatz, Nathan, 1845—52nd St., Brooklyn, N. Y.
Shen, C. Mayo, 18 an Check L8, Scott Rd., Shanghai, China.
Uline, Wm. A. Northern Elec. Co., Guy & Notre Dame Sts., Montreal, Que., Can.

# Local Meetings

## Past Section Meetings

**Akron**

Electrical Installations of Guggenheim Institute, by Prof. J. T. Walther, Akron Univ. Demonstration in airport lighting upon the arrival and departure of a tri-motor plane from Pittsburgh. Different Types of Wind Tunnels, by Dr. Theodore Troller, resident director of Guggenheim Institute. Demonstrations. Oct. 11. Att. 73.

**Atlanta**

The Engineer's Place in the Sun, by Prof. W. E. Freeman, Univ. of Kentucky, vice-pres., A.I.E.E. Oct. 7. Att. 45.

**Boston**

Inspection trip through the new laboratories at Mass. Inst. of Tech. Oct. 19. Att. 90.

**Cincinnati**

Symmetrical Components, by A. W. Lewis, Westinghouse Elec. & Mfg. Co. Illustrations. Oct. 13. Att. 65.

**Cleveland**

Electric Shock, by Dr. W. B. Kouwenhoven, Johns Hopkins Univ., vice-pres., A.I.E.E. Oct. 20. Att. 102.

**Columbus**

Air Conditioning Development, by R. E. Robillard, Frigidaire Corp. Oct. 28. Att. 36.

**Connecticut**

Seeing, by Dr. Matthew Luckiesh, Gen. Elec. Co. Joint meeting with Engrs. Club of Hartford. Sept. 29. Att. 200.

Design and Manufacture of Small Motors and Generators, by D. G. Shepherd, E. W. Borggrafe, and W. H. Haines, all of the Electric Specialty Co. Oct. 26. Att. 59.

**Dallas**

Overhead Conductor Vibration, by R. A. Monroe, Aluminum Co. of America. Illustrated. Oct. 17. Att. 61.

**Denver**

The Human Side of Constructing Engineers, by Prof. F. V. Bliss. Dinner. Oct. 21. Att. 24.

**Detroit-Ann Arbor**

The Public Utility Dollar—Where It Comes From and Where It Goes, by A. C. Marshall, Detroit Edison Co. Dinner. Oct. 18. Att. 160.

**Fort Wayne**

The Dependence of Air Transportation on the Electrical Engineer, by C. F. Green, Gen. Elec. Co. Illustrated. Oct. 11. Att. 115.

**Houston**

Industrial Engineering and the Electric Utilities, by L. K. Del'Homme, Houston Lighting & Power Co. Dinner. Oct. 26. Att. 13.

**Indianapolis-Lafayette**

Low Voltage Circuit Protection Without the Use of Fuses in Combination With the Deion Principle of Arc Extinction, by H. G. Nichols, Westinghouse Elec. & Mfg. Co. Illustrated. Oct. 18. Att. 72.

**Kansas City**

The Design and Purpose of Electric Dispatching Boards, by T. V. White, Amer. Automatic Elec. Sales Co.; Television, by G. L. Taylor, First National Television Co. Demonstrations. Oct. 25. Att. 65.

**Lehigh Valley**

Electrons at Work and at Play, by Phillips Thomas, Westinghouse Elec. & Mfg. Co. Demonstrations. Prize of $25 awarded to W. H. Lesser for the best local technical paper. Joint meeting with Engrs. Club, held at Hotel Traylor, Allentown. Oct. 14. Att. 650.

**Los Angeles**

The Industrial Aspect, by W. L. Moreland. Moreland Motor Truck Co.; The Transportation Aspect, by Frank Carr, Pacific Elec. Co.; The Financial Aspect, by O. E. Monnette. Bank of America. Joint meeting with A.S.C.E., A.S.M.E., and A.I.M.E. Oct. 12. Att. 600.

**Louisville**

Inspection trip to Dix River Dam. Oct. 29. Att. 35.

**Lynn**

Chasing News With a Camera, by A. H. Blackington. Illustrated. Oct. 19. Att. 475.

Professor Nichols, of Tufts College, conducted an inspection trip to Nahant, Beach Bluff, and Salem to show local geological formations of particular interest. Oct. 29. Att. 35.

The Solar Eclipse, by Dr. D. H. Menzel, Harvard Observatory Staff. Nov. 2. Att. 800.

**Madison**

The Edgewater Plant, by W. S. Campbell, Wisconsin Pwr. & Lt. Co. Dinner. Nov. 2. Att. 42.

**Memphis**

Activities of the War Industrial Board, by Major E. C. Kelton, U.S. Engineers' Corps. Oct. 24. Att. 33.

**Mexico**

Annual banquet. Oct. 29. Att. 40.

**Minnesota**

Economics in Relation to Public Utilities, by Prof. J. M. Bryant, Univ. of Minnesota. Oct. 27. Att. 20.

**New York**

The Utility's Problem, by H. R. Searing, N. Y. Edison and United Elec. Lt. & Pwr. Co.; The Contractor's Problem, by Allen Coggeshall, Hatzell & Buehler, Inc. Power group meeting. Oct. 14. Att. 400.

Air Conditioning as a Potential Factor in National and World Economics, by W. H. Carrier, Carrier Engg. Co. Oct. 26. Att. 450.

World-Wide Telephony, by Bancroft Gherardi, Amer. Tel. & Tel. Co. Communication group meeting. Nov. 1. Att. 525.

**Niagara Frontier**

Rational Control of Motor Starting Currents, by R. T. Henry, Buffalo, Niagara & Eastern Pwr. Co. Oct. 21. Att. 65.

**Oklahoma City**

Vibration of Overhead Conductors, by R. A. Monroe, Aluminum Co. of Amer. Oct. 20. Att. 54.

**Philadelphia**

Adventures in Science, by E. L. Manning, Gen. Elec. Co. Oct. 10. Att. 125.

**Pittsburgh**

Electric Shock, by Dr. W. B. Kouwenhoven, Johns Hopkins Univ., vice-pres., A.I.E.E. Oct. 19. Att. 114.

**Pittsfield**

Japan, China, and the White Man, by Upton Close. Nov. 1. Att. 1100.

**Portland**

Annual dinner with six speakers. Joint meeting with N.E.L.A. Oct. 18. Att. 57.

**Providence**

General Electric Oil Furnace, by F. A. Durkin, Gen. Elec. Co. Oct. 11. Att. 60.

The Narragansett Electric Distribution System, by Orie Van Rye, New England Pwr. Engg. and Serv. Corp. Nov. 9. Att. 60.

**St. Louis**

Oil-Filled, Self-Cooled Transformers by Temperature, by H. B. Keath, Wagner Elec. Corp. Oct. 19. Att. 69.

**San Antonio**

San Antonio's New Automatic Telephone System, by B. D. Hull, Southwestern Bell Tel. Co. Inspection trip through the plant. Sept. 26. Att. 142.

Vibrations in Overhead Conductors, by R. A. Monroe, Aluminum Co. of Amer. Demonstrations. Oct. 18. Att. 42.

**San Francisco**

The European Viewpoint, by Frank Copley; Proposed Boulder Dam Transmission Line, by Bradley Cozzens, Bureau of Pwr. & Lt. of the City of Los Angeles. Dr. J. F. Carroll explained the laboratory equipment and tests to be witnessed. Oct. 19. Att. 250.

**Saskatchewan**

Banquet. Joint meeting with E.I.C. Oct. 21. Att. 22.

**Schenectady**

Methods of Obtaining Colored Motion Picture Films, by J. G. T. Gilmour, Gen. Elec. Co. Oct. 6. Att. 125.

**Sharon**

Electrons at Work and at Play, by Dr. Phillips Thomas, Westinghouse Elec. & Mfg. Co. Film—"Dynamite." Oct. 21. Att. 230.

**Springfield**

Total Eclipses of the Sun, by B. V. K. French, Amer. Bosch Magneto Corp. Illustrated. Oct. 10. Att. 71.

**Toledo**

Executive committee meeting. Oct. 6. Att. 8.

Soviet Russia, by Mr. Buchenburg, Electrical Autolite Co. Oct. 12. Att. 18.

Fundamentals of Magnetism, by W. W. Cummins, Toledo Edison Co.; Effects of Electric Shock, by Dr. W. B. Kouwenhoven, Johns Hopkins Univ., vice-pres., A.I.E.E. Oct. 21. Att. 160.

**Toronto**

Recent Developments in Air Breaker Switching, by W. Gilson, Eastern Pwr. Devices. Oct. 14. Att. 90.

The Foundations of Science, by W. F. Sutherland, Toronto Hydroelectric System. Oct. 28. Att. 50.

**Washington**

Light, by Prof. L. D. Bliss, Bliss Electrical School. Oct. 11. Att. 90.

**Worcester**

Illumination, by W. E. Haycock, Gen. Elec. Co.; Radio, by Prof. H. H. Newell, Worcester Poly. Inst.; Air Conditioning, by E. D. Learned, Worcester Elec. Lt. Co.; Electric Heating of Buildings, by W. A. Sutphen, New England Pwr. Engg. & Serv. Corp.; Telephone, by J. W. Kidder, New England Tel. & Tel. Co. Dinner meeting. Oct. 18. Att. 43.

## Future Section Meetings

**Boston**

December 13—Lightning Arrestors, by Messrs. Corney and Haynes.

January 10, 1933.—International Communication.

**Cleveland**

December 15—Submarine Treasure Hunting With Underwater Lamps, by E. W. Beggs, Westinghouse Lamp Co. Joint meeting with Ill. Engg. Soc., at Westinghouse Lighting Studios. Edgewater Park.

January 19, 1933—Social meeting.

**Detroit-Ann Arbor**

December 13, at Detroit, Mich.—Electric Motors and Their Applications, by A. M. Dudley, Westinghouse Elec. & Mfg. Co.

January 17, 1933, at Detroit, Mich.—Extending Our Frontiers Through Research and Engineering, by H. P. Charlesworth, pres., A.I.E.E., vice-pres., Bell Tel. Labs., Inc.

**Fort Wayne**

December 7, at Chamber of Commerce.—Design and Application of Demand Meters, by H. M. Witherow, Gen. Elec. Co.; Performance Calculations for Special Stationary Apparatus, by M. L. Schmidt, Gen. Elec. Co.

January 17, 1933, at Home Tel. & Tel. Auditorium.—Dial Controlled Robots, by H. M. Bruckart, Home Tel. & Tel. Co.; A New Development in Oven Control, by R. M. Hartigan, Gen. Elec. Co. Inspection of the Fort Wayne Telephone Exchange.

**Lehigh Valley**

December 9, at Berkshire Hotel, Reading, Pa.—Three Years Progress in Field Investigation With Artificial Lightning, by K. B. McEachron, Gen. Elec. Co.; Reversed Refrigeration for House and Water Heating, by G. Wilkes, W. F. Barstow Co.

**Pittsfield**

December 6—Rovings of a German Sea Raider, by Captain Julius Lauterbach.

December 20—Theory of the Expanding Universe, by Dr. Harlow Shapley.

January 3, 1933—By Air to Inca Land, by Robert Shippee.

January 17, 1933—Modern Railway Electrification—With Special Reference to Pennsylvania System, by J. V. B. Duer, Pennsylvania RR. Co.

**Toledo**

December 16—Lighting the Modern City, by L. A. S. Wood, Westinghouse Elec. & Mfg. Co.

January 13, 1933—Air Conditioning, by H. B. Matzen, Carrier Corp.

**Toronto**

December 16—Applications of Synchronous Motors, by Leech-Porter.

January 19, 1933—Coordination of Insulation, by W. W. Lewis.

January 27, 1933—Astronomy and the Dunlap Observatory, by Prof. Chant, Univ. of Toronto.

## Past Branch Meetings

**University of Alabama**

The Commercialization of the X-Rays, by W. K. Price, student. Oct. 16. Att. 29.

The Power Distribution of Transit Lines, by F. B. Gaines, student. Oct. 24. Att. 24.

**University of Arkansas**

Benefits of Membership in the A.I.E.E., by Dean W. N. Gladson. Oct. 6. Att. 37.

A review of the papers and events at the Conference on Student Activities, held at the University of Oklahoma, was given by several students. Oct. 27. Att. 32.

The American Engineer in Russia, by G. Smith, student; Investigation of Single Energy Transients, by W. D. Thornberry, student; Engineering From the Sales Viewpoint, by C. E. Bradley, Gen. Elec. Co. Nov. 3. Att. 34.

**Armour Institute of Technology**

Discussion of Branch activities. Oct. 7. Att. 31.

Air Conditioning, by M. J. Maiers, Central Station Institute. Illustrated. Oct. 21. Att. 35.

Motion pictures. Nov. 4. Att. 30.

**University of British Columbia**

Western Electric Speech Input Equipment, by W. Smith, student; Photo-Telegraphy, by L. Rader, student. Oct. 13. Att. 13.

**Polytechnic Institute of Brooklyn**

The Applications of the Photoelectric Cell in the Holland Tunnel, by Prof. Robin Beach. Refreshments. Nov. 2. Att. 65.

**California Institute of Technology**

M. S. Hodge, chmn., gave a report of the Pacific Coast Convention held in Vancouver. Prof. R. W. Sorensen, counselor, gave a summary of the work carried on by the A.I.E.E. Oct. 14. Att. 26.

H. C. Fracker, Bell Tel. Labs., Inc., gave a demonstration and lecture of the newly developed vertical cut phonograph records, recording, and amplification system. Oct. 20. Att. 300.

**University of California**

The Application and Operation of the Teletypewriter, by R. Tibbetts and V. Tonjes, students. Motion pictures. Sept. 21. Att. 51.

Initiation banquet. Problems Found in the Engineering, Social, and Economic Fields, by Dr. Ira B. Cross. Sept. 23. Att. 57.

**Carnegie Institute of Technology**

The Development of the Carnegie Tech. Branch of the A.I.E.E., by Prof. G. Porter, counselor; Place of an Engineer in Engineering Society, by Dr. W. R. Work; Benefits I Have Derived From Membership in the A.I.E.E., by Dr. C. E. Skinner, Westinghouse Elec. & Mfg. Co. Oct. 17. Att. 27.

Testing Railroad Tracks by Means of the Sperry Railroad Car, by Dr. W. B. Kouwenhoven, Johns Hopkins Univ., vice-pres., A.I.E.E. Oct. 19. Att. 90.

**Case School of Applied Science**

Prof. J. R. Martin described his work in connection with the eclipse. Oct. 21. Att. 31.

**Catholic University of America**

Election of officers: J. Springman, pres.; R. Bourne, vice-pres.; T. J. Nally, secy.; F. Hurson, treas. Oct. 4. Att. 20.

**Clemson Agricultural College**

Executive meeting. Oct. 4. Att. 51.

A Modern European Power Plant, by M. G. Miller, student; The Development of Electrical Machinery in the U.S., by H. A. Clayton, student; current events, by E. B. Shaw, student. Oct. 25. Att. 34.

**Colorado Agricultural College**

Prof. G. Z. Dimitroff outlined his trip to New England to photograph the total eclipse of the sun. Joint meeting with A.S.M.E. branch. Oct. 24. Att. 26.

**University of Colorado**

The Construction, Management, and Functions of the A.I.E.E., by Prof. W. C. DuVall, counselor, and Prof. M. S. Coover, District secy. A.I.E.E. Oct. 5. Att. 53.

My Vacation Tour of France, Switzerland, Germany, and England on a Bicycle, by J. M. Evans, student. Illustrated. Joint meeting with A.S.M.E. Branch. Oct. 19. Att. 52.

**Cornell University**

Political Issues and the Stock Market, by J. W. McWilliams, student; The Making of Lateral Cut Records on Aluminum Disks, by J. W. Conn, student. Oct. 28. Att. 25.

**University of Denver**

Electrical Engineering and Senior Branch of A.I.E.E., by Prof. R. E. Nyswander, counselor. Oct. 11. Att. 20.

Inspection trip through the terminal station and two substations of the Public Service Co. of Colo. Att. 12.

**University of Detroit**

Lighting of the Campus and Power Factor Correction, by Prof. H. O. Warner, counselor. Films—"Vacuum Tube Synchronization," "Synchronizing Machine Construction." Oct. 27. Att. 42.

**Duke University**

The Advantages and Disadvantages of Double Conductor Transmission Lines, by D. E. Cook, student; The Expansion of Electrical Engineering Fields, by W. J. C. Brown, student. Oct. 18. Att. 27.

Fallacies of Mathematics, by Wm. Karpinsky, student; The Engineer's Place in the Sun, by Prof. W. E. Freeman, Univ. of Kentucky, vice-pres., A.I.E.E. Nov. 3. Att. 33.

**University of Florida**

The Florida Portland Cement Plant at Tampa, Fla., by J. B. Smith, student; Things of Interest in the Bell Telephone Laboratories, by E. L. Stuhrman, student. Oct. 18. Att. 40.

**University of Idaho**

Films—"Manufacturing Mazda Lamps," and "Power Transformers." Dinner. Oct. 4. Att. 26.

**University of Illinois**

The Theory of Oscillatory Circuits, by Mr. Veach, student. Film—"The Electric Ship." Oct. 12. Att. 127.

**University of Iowa**

R.O.T.C. Summer Camp Life, by T. R. MacDougall, student. J. W. Blessing elected secy. Oct. 5. Att. 31.

General discussion and inspection of the new dial telephone exchange. Oct. 12. Att. 32.

Dial Telephone Systems, by H. Hammond, student; Elimination of Radio Interference, by A. Shradel, student. Oct. 26. Att. 38.

Flood Lighting, by C. Bartholow, student; Guiding Airplanes by Radio, by Wm. Benineosa student. Nov. 2. Att. 36.

**University of Kentucky**

Election of officers: R. H. Gray, pres.; E. W. Graham, secy.-treas. Sept. 21. Att. 48.

**Lehigh University**

Airport Lighting, by W. D. Hickman, student; My Experiences at Harvard and M.I.T., by Prof. J. L. Beaver. Committees appointed. Oct. 7. Att. 50.

The Cosmic Ray, by Dr. R. A. Millikan, Calif. Inst. of Tech. Oct. 26. Att. 780.

**Lewis Institute**

Prof. F. A. Rogers, counselor, outlined the privileges and advantages of student enrolment in the A.I.E.E. Oct. 18. Att. 120.

Election of officers: I. R. Ekstrom, pres.; Walter Bohne, secy.-treas. Nov. 3. Att. 86.

**Louisiana State University**

Discussion. Nov. 3. Att. 21.

**University of Louisville**

Dix River Dam Electric Power Project, by Mr. Jefferson, student. Film—"Pathways of Progress." Nov. 7. Att. 23.

**Michigan College of Mining and Technology**

Prof. G. W. Swenson, counselor, outlined the advantages of membership in the A.I.E.E. Oct. 13 Att. 42.

Distribution, by I. H. Gronseth, Board of Water & Elec. Lt. Comm. Oct. 19. Att. 46.

Inspection trip to the Howell Motors Co. Oct. 26. Att. 17.

Ultra short wave radio demonstration. Nov. 2. Att. 41.

**University of Michigan**

Election of officers: J. M. Lyon, chmn.; G. Leland, vice-chmn.; I. J. Sattinger, secy.; D. J. Carr, treas. Film—"Nature's Frozen Credits." Oct. 17. Att. 54.

**Milwaukee School of Engineering**

Electric Sectional Drive for Paper Making Machinery, by E. H. Laabs, Cutler-Hammer Mfg. Co. Oct. 12. Att. 76.

**University of Minnesota**

Experiences at Oxford, by Fred Hovde. Oct. 12. Att. 110.

**Mississippi State College**

Discussion. Oct. 12. Att. 30.

**University of Missouri**

Synchronous Motors, by C. Haines and F. Hubbell, students. A. Coffman, student, outlined the Conference on Student Activities, held at the Univ. of Okla. Nov. 2. Att. 27.

**Montana State College**

X-Ray and Cathode Ray Tubes in Biological Service, by L. Ambrose; The Engineer in a Changing Society, by R. V. Bauer; Underground Conduit Construction, by J. Cromer; A Noiseless and Flameless High-Voltage Fuse, by Loran Eisele; Erecting Poles With Conductors Attached, by C. L. Grebe, all students. Oct. 13. Att. 86.

Welding Steel Structures, by Rex Wyman; A 115,000 Kw. Turbo-Alternator, by E. Rothaus; Radio and Television, by T. Degenhart and J. Lightfoot, all students. Oct. 20. Att. 89.

The Characteristics of Some Miniature Lamps, by D. A. Nauck; Highway Lighting, by J. Antonich; Visiting Butte's Greatest Industry, by M. Axelson; Further Research in Injuries From Electric Shock, by C. Bergland, all students. Oct. 27. Att. 95.

**University of Nevada**

Discussion. Oct. 7. Att. 7.

**Newark College of Engineering**

Members attended the George Washington Bicentennial celebration, sponsored by the joint professional engineering societies of Essex County, at which Roy V. Wright, editor of *Railway Age*, spoke on George Washington, The Engineer. Oct. 19. Att. 25.

**University of New Hampshire**

Film—"Anthracite." Sept. 24. Att. 31.

Testing Paper for Electrical Insulation, by H. T. Dickson; Correcting Readings Taken on Small Power Motors, by A. E. Dogan; Eddy Currents, by H. W. Feindel; E. Horne covered the question box in Electric Journal, all students. Oct. 1. Att. 27.

Nothing More Modern, by H. W. Machon; An Ordeal by Water and Eddy Currents, by O. Abbiatti; Mechanical Vibration Research, by A. F. Allen; The Clock on the Mantel, by E. L. Huse, all students. Oct. 15. Att. 32.

Types of Supply for Three Wire Systems, by C. W. Quimby; Fusing the Neutral of a Three Wire System, by H. W. Hamm; The Homopolar or Unipolar Generator, by R. C. Loeschner; Gun Recoil Control, Metalized Wood, and Invisible Wire Hair, by M. H. Sargent, all students. Oct. 29. Att. 29.

**College of the City of New York**

Industrial Control Problems, by O. H. Diefendorfer, Gen. Elec. Co. Oct. 20. Att. 51.

Discussion. Oct. 27. Att. 29.

**New York University**

Prof. H. N. Walker, counselor, outlined future plans. Oct. 14. Att. 18.

The Photoelectric Cell, by Mr. Zdanowitz, student; Push-Pull Amplifiers, by Mr. Christie, student. Oct. 28. Att. 20.

**North Carolina State College**

The Electric Power Development in Syria, by J. R. Salem, student; Engineering Topics of the Day, by C. M. Smith, Jr., student. Oct. 18. Att. 42.

Counting Salmon in Alaska, by J. S. Culbertson, student; Engineering Topics of the Day, by C. M. Smith, Jr., student; Technocracy, by F. E. Brammer, student. Nov. 1. Att. 35.

**University of North Carolina**

The Aims, Functions, and Organization of the A.I.E.E., by Prof. J. F. Lear, counselor; The A.I.E.E. Convention at Cleveland, by Prof. E. W. Winkler. Oct. 13. Att. 50.

**University of North Dakota**

Caissons, by Boyd Begg, Raymond Concrete Pile Co. Oct. 5. Att. 21.

Talk by P. J. Montgomery, Northern States Pwr. Co. Oct. 19. Att. 21.

Film—"Electricity Goes to Sea." Nov. 3. Att. 17.

**University of Notre Dame**

Electrical Applications to Municipal Government, by E. A. Qualls, supt., City Electrical Dept. of South Bend. Oct. 19. Att. 70.

Making a Living With an Engineering Education, by J. P. Kennedy; Patents—How to Get One and the Cost, by Leo Hanlon, student; Electrification of the Great Northern Railway, by John Land, student; P. McCaffary, student, gave the bi-weekly review of current engineering news. Nov. 2. Att. 54.

**Ohio State University**

History and Founding of the A.I.E.E., by Prof. F. C. Caldwell, counselor; The Engineer in Industry, by Prof. Bibber. Oct. 13. Att. 40.

**Ohio University**

Prof. A. A. Atkinson, counselor, and J. Hoskinson, chmn., outlined the advantages of membership in the A.I.E.E. Oct. 10. Att. 23.

Remote Control of Ships From Land Stations, by W. Cooper and C. Eddy, students. Oct. 19. Att. 14.

How Electricity Received Its Start in Athens, by Prof. A. A. Atkinson, counselor. Nov. 2. Att. 15.

**University of Oklahoma**

Prof. F. G. Tappan, counselor, explained student enrolment in the A.I.E.E. Oct. 5. Att. 18.

**Oregon State College**

Acceptance Test of the Rock Island Hydraulic Unit, by J. F. Spease, Gen. Elec. Co. Oct. 20. Att. 39.

**Pennsylvania State College**

Smoker. Oct. 5. Att. 60.

**Rensselaer Polytechnic Institute**

Construction of the New Transmission Line Between Albany and Westchester Counties, by A. G. Stockrott, N. Y. Pwr. & Lt. Corp. Oct. 18. Att. 350.

**Rhode Island State College**

Film—"Nature's Frozen Credits." Oct. 13. Att. 25.

Michaelson's Experiments on the Velocity of Light, by Prof. Wm. Anderson, counselor. Oct. 20. Att. 16.

Industrial Applications of the Thyratron Tube, by E. A. Hancock and A. J. Moore, both of the General Elec. Co. Nov. 2. Att. 175.

**Rutgers University**

Discussion. Oct. 4. Att. 19.

Practical Testing of Telephone Cables, by L. M. Leeds, Amer. Tel. & Tel. Co. Oct. 18. Att. 19.

Film—"Conowingo." Nov. 1. Att. 41.

**University of Santa Clara**

Industrial Achievements in Other Countries, by Warren McBride. Joint meeting with A.S.M.E. Branch. Oct. 7. Att. 66.

**University of South Carolina**

Television, by G. W. Arrants; The Liner That Cannot Roll, by T. J. Bennett; Electric Aids to Medicine, by S. A. Black, all students. Oct. 10. Att. 33.

Night Lighting for Outdoor Sports, by D. W. Cardwell; Radio and Dynamite Find Earth's Secret Riches, by T. H. Coughman; Electric Ship California, by C. L. Bradley, all students. Oct. 17. Att. 34.

More Power to Canada, by R. F. Cuthbertson, student; Photoelectric Control of Paper Cutter Register, by N. J. Christensen, student. Oct. 24. Att. 35.

Radio Activity, by M. Garris; Welding, by L. Folson, Overseas Telephony, by A. G. Daniels, all students. Oct. 31. Att. 33.

**South Dakota State School of Mines**

Discussion. Oct. 12. Att. 25.

Albert Hall elected vice-chmn., and Charles Reed elected secy.-treas. Oct. 21. Att. 26.

**University of Southern California**

The Essentials of a Successful Engineer, by Mr. Rowley, Los Angeles Bureau of Water and Power. Sept. 21. Att. 26.

Engineer and His Social Aspects, by Dean Bacon. Sept. 28. Att. 20.

High Head, Remote Control, Pumping Station at Boulder Dam, by W. F. Grimes, Westinghouse Elec. & Mfg. Co. Oct. 5. Att. 29.

Banquet. Oct. 13. Att. 24.

**Southern Methodist University**

Recent Developments in the Metering of Electrical Energy, by M. P. Jones, student. Oct. 19. Att. 8.

**Stanford University**

Events at the Pacific Coast Convention, held in Vancouver, outlined by several students. Oct. 11. Att. 30.

**Stevens Institute of Technology**

Rolls Royce Type R Engine Used in the Schnieder Trophy Races, by Prof. E. Fezandie. Oct. 7. Att. 44.

**Syracuse University**

Crystal Control of the Vacuum Tube, by A. Adams, student; Radio Beacons, by C. P. Bower, student. Oct. 11. Att. 23.

Power Transmission, by J. S. Brzostek, student; X-Rays, by R. Bradshaw, student. Oct. 18. Att. 23.

Power Transmission and Distribution in Syracuse, by A. Carley, student; Static Elimination in Radio Sets, by C. M. Crysler, student. Oct. 25. Att. 20.

Inspection trip to hydroelectric power plants at Salmon River and Oswego. Nov. 1. Att. 21.

Harmonic Analysis, by Prof. C. W. Henderson, counselor; Electrical Home at Present, by L. E. Dawley, student; Electrical Home of the Future, by N. F. Emig, student. Nov. 8. Att. 21.

**University of Tennessee**

Discussion of future activities. Oct. 5. Att. 20.

Films—"Sugar Cane Industry in Cuba" and "Construction of the Panama Canal." Oct. 19. Att. 25.

Characteristics of a Mercury-Vapor Tube, by A. C. Seletzley and S. T. Shevki, presented by Wiley Patton, student. Review of current events given by Mr. Lerch, student. Nov. 2. Att. 14.

**Texas A. & M. College**

Election of officers: G. H. Samuels, chmn.; W. E. Steele, vice-chmn.; J. I. Walton, secy.-treas. Oct. 4. Att. 80.

Why Modern High Speed Railway Service Is Possible, by H. B. Yarbrough; Stray Losses of a D.C. Dynamo, by J. K. Jones; Permeability Tuning of Broadcast Receivers, by C. C. Johnston; An Ultra Short Wave Transmitter, by G. C. Hutcheson; Lightning Protection, by A. J. Ismeal, all students. Oct. 11. Att. 26.

Film—"Conowingo." Oct. 27. Att. 90.

**Texas Technological College**

The Aims and Purposes of the Student Branches, by J. Preston Conner, student. The Advantages of a Technical Education, by Dr. Bradford Knapp. Oct. 5. Att. 29.

**University of Texas**

W. B. Hurt elected corresponding secy. Oct. 5. Att. 28.

Some Fundamentals on Inductive Coordination, by David Sussin, student. Oct. 13. Att. 12.

**University of Utah**

Film—"A Trip Through the G. E. Plant." Oct. 26. Att. 36.

New Transmitter Equipment at Station KSL, by E. G. Pack, radio engr. at that station. Nov. 2. Att. 38.

**University of Virginia**

Discussion. Oct. 14. Att. 14.

The Engineer's Place in the Sun, by Dean W. E. Freeman, Univ. of Kentucky, vice-pres., A.I.E.E. Oct. 20. Att. 24.

**Virginia Military Institute**

Armature and Stator Windings, by N. W. Dingman; Elevator Service in Our Modern Skyscrapers, by J. T. Taylor; Improving the Prestige of the Engineering Profession, by G. S. Bernard; The Story of Frequency, by C. E. Schoonover, all students. Sept. 23. Att. 111.

Nothing More Modern, by R. S. Singleton; Electric Locomotives, by J. M. Troutt; Motor Car Design, by G. C. Wilson; Guiding Airplanes by Radio, by T. R. Wise, all students. Oct. 1. Att. 106.

**Virginia Polytechnic Institute**

Film—"Conowingo." Oct. 13. Att. 168.

The Engineer's Place in the Sun, by Prof. W. E. Freeman, Univ. of Kentucky, vice-pres., A.I.E.E. Oct. 21. Att. 66.

Highway and Street Lighting, by W. E. DeBrick; Reversed Refrigeration, by G. Giles, Jr.; Too Many Engineers, by E. H. Farley; Communication as an Aid to Transportation, by J. L. Brown; Philadelphia's New Electrical Structure, by R. P. Haskins, all students. Oct. 27. Att. 42.

**State College of Washington**

General discussion. Oct. 14. Att. 25.

**University of Washington**

Frequency Modulation of Radio Waves, by E. D. Scott, student. Oct. 13. Att. 25.

Business Conditions as They Affect the Student, by L. E. Karrer, Puget Sound Power & Light Co. Oct. 20. Att. 21.

Film—"Nature's Frozen Credits." Oct. 27. Att. 23.

**West Virginia University**

Taming a Tropic Torrent, by R. H. Colborn; Longest Telephone Cable in the World, by U. A. Chapman; Is Radio Making Us a Race of Morons? by J. G. Henderson; Type 57 Radio Tube, by N. I. Hall; Experience in Testing Porcelain, by J. E. Wallace; Thermostatic Control on Motor Circuits, by M. B. Tolley; Life of Benjamin Carver Lamme, by R. Marshall, all students. Oct. 10. Att. 22.

Synchronous Motor Effect in Induction Motors, by F. Q. Brown; Wave Frequency Meter, by G. F. LeFeure; Circuit Diagrams, by J. Millard; Little Water Passes Eagle Pass, by E. C. McMillan; S. S. Manhattan, by C. B. Sims; Communication at National Convention, by P. M. Vannoy; Constant Current Street Light Circuit, by L. P. Lovett, all students. Oct. 17. Att. 26.

Testing Surge Generators, by R. Caddock; Biography of Charles P. Steinmetz, by G. Henderson; W. Va. University Heating Plant, by R. R. McCue; Pearl Street Generating

Plant, by E. J. Williams; Public Address System, by W. D. Hall; Modern Lighting in Interurban Cars, by L. H. Winger, all students. Oct. 24. Att. 24.

Description of an Alexandrean Alternator, by N. I. Hall; 75-Kv Submarine Cable for Deepwater Station, by J. E. Wallace; Power Eliminators, by M. B. Tolley; Diesel Power Stations, by R. Marshall; Hydrogen as a Cooling Medium for Electrical Machinery, by R. H. Colborn; Turbine Design Here and in Great Britain, by L. W. Hall; Methods of Controlling the Speed of Induction Motors, by W. C. Monteith, Jr., all students. Oct. 31. Att. 25.

### University of Wisconsin

Moving pictures. Oct. 19. Att. 28.

# Employment Notes

## Of the Engineering Societies Employment Service

## Men Available

### Construction

ELEC. CONSTRUCTION ENGR with 10 yr practical experience in elec. construction on new and old buildings, including estimating, field engg. and designing. Have had complete charge of elec. construction on many buildings in New York City and can furnish the best of references. Available at once. A-[illegible]50.

CONST. MAIN. ENGR, 36, married, factory layout installation, inventive, new ideas pertaining to elec. and steam mach. conveyors, switchboard design. Power plant layout and installation, const. transmission, also good in marine work. Location anywhere. D-1622.

E.E. GRAD., Ohio State, 1929, married, 29. Three yr communication training with Ohio Bell Tel. Co., including outside line and cable construction, subway, pole line, maintenance, installation and testing experience. Not afraid of hard work. References furnished. Available immediately and will go anywhere. D-1674.

GRAD. E.E., 29, five yr supervisory construction, design, estimating and field engg experience on super-power plants and substations; 4 yr industrial power plant operation. Elec. construction and maintenance experience; railway electrification construction experience. C-4428.

### Design and Development

DISTRIBUTION, DESIGN OR MANUFACTURING ENGR, E.E. grad. 27, married. Six yr experience with Westinghouse on distribution, special and small transformer designs. Desires responsible position as transformer design, development or mfg. engr or e.e. for mfr., utility, holding company or where knowledge of big company's methods may be used. Available immediately. D-963.

E.E., univ. grad., elec. power experience, both design work and construction and maintenance work, desires position with power or mfg. organization offering permanent or temporary position in office or field. B-1923.

E.E., univ. grad., 34, single, 7 yr experience in drafting design, installation distribution networks, power companies and industrial plants. Five yr with communication engg in design, manufacture of testing equipment. Good mathematician, good draftsman. French, German, Spanish. Desires responsible position. Anywhere. D-1514.

E.E. GRAD., 33, 10 yr experience in the elec. industry, 8 yr actual experience on the design of motors and fans. Capable of assuming full responsibility for development of a-c and d-c motors and generators. Highest references. Middlewest preferred. C-5353.

ELEC.-MECH. ENGR with metallurgical knowledge. College grad. with post grad. study. Age 30, married. Westinghouse design training. Six yr experience design elec. circuits and mech. details of control apparatus, specialized in elevator equipment. Interested in alloy welding research. Location immaterial. Available on short notice. C-9638.

ELEC. AUTOMOTIVE ENGR, desires position with medium size manufacturer on design and development of automotive accessories. Have patented 19 automotive accessories. Ten yr experience and at present experimental and automotive engr on fleet of 2,300 trucks, etc. Technical education. age 32. Location New York or Philadelphia. D-1653.

E.E., 34, 10 yr experience covering design, cost estimating, and equipment specifications of power plants, industrial buildings, copper and oil refineries, substations and transmission lines. Also one yr as assist. research engr with cable co., and one yr as elec. tester with elevator co. Speak German. C-5473.

ELEC. DESIGN ENGR, 31, single, 8 yr experience in design and analyzation of manual and automatic telephone circuits. Experience on relay and switch controlled circuits for signaling or alarms. Available at once. D-1647.

E.E. GRAD., 27, single, desires position in design, development or teaching. One yr testing d-c machinery and controls, 4 yr development of outside plant hardware for telephone use. Available at once. Salary and location open. D-1305.

E.E. GRAD. of Purdue, 18 yr experience in railway, power plant, substations, transmission line, steel mill and paper mill design, construction and operation. G. E. test. Valuation, appraisal, invention. Two yr sales. Available now. Location immaterial. C-8256.

ELEC. DESIGNER, 32, married, equivalent of a college education, best of references, 14 yr experience in design of hydroelectric and steam power plants, automatic railway, high and low tension substations and low tension network systems. Available at once. Location immaterial. B-8628.

### Executives

INDUS. CONTROL AND SWITCHGEAR ENGR, Cornell graduate, married. Practical technical experience of 15 yr estimating, design, building, installation and operating of manual and automatic control applied to productive and central station industries. D-1273.

AVAILABLE AT PRESENT e.e. grad. 1920. Twelve yr. Bell System experience, 2 months' G.E. test. Married, 2 children. D-1617.

E.E., grad., 33, single, 9 yr experience. G. E. test and switchboard engg. Is thoroughly familiar with relay, meter and power circuits together with a broad knowledge of power plant and industrial elec. requirements. Can locate anywhere. B-8365-4018-Chicago.

E.E. GRAD., 37, married, with 15 yr experience covering Westinghouse test and public utility operation, finance and valuation. Familiar with elec., gas, and water properties. Prefer executive position with public utility. Location immaterial. D-1639.

ELEC.-MECH. ENGR; univ. grad., married, 34; 4 yr steel mills, one yr G. E. test, 3 yr public utility, 4 yr industrials. Estimates, designs, specifications, developments, tests, construction, supervision. Steam hydraulic power plants, manual automatic substations, converter stations, industrial buildings, overhead underground transmission systems, high low voltage equipment. Available immediately. C-2907.

ASST. ENGR, 14 yr experience, 34, married. Nine yr with 2 large eastern utilities, full engg charge in the installation and maintenance of substations and generating stations. Five yr with leading mfgr., design, development and production engg, outdoor substations and substation and transmission switching and protective equipments. D-1644.

B.S. in E.E., 26, single. Three yr general engg experience, including erecting and testing power equipment; conducting illumination and voltage surveys. Peculiarly fitted for e.e. service in Spanish speaking countries; can speak Spanish and English equally well. D-1462.

GRAD. ENGR, age 31. Ten yr experience in public utility and industrial field. Most of time on standardization, valuation and other problems of public utility economics including future expansion and budgetary control. Am conscientious worker and will make good man for some utility wishing to study changing economic conditions. B-6934.

ELEC. ENGR, married, E.E., M.E. [illegible]2 yr experience, designing, construction power plants, substations, transmission, distribution systems, and industrial plants. Three yr charge purchasing engineering equipment, foreign interests. Three yr executive experience charge engineering department large utility syndicate. English, German, Russian, Armenian, Turkish languages. Available immediately. [illegible]

GRAD. E.E., B.Sc., Master Bus. Adm., studies toward M.Sc., 36, single; 15 yr broad experience; power plant, substation design and wiring diagrams; appraisals; automatic telephone equipt., cable inspection and specs.; test work on motors and gens.; instructor elec. lab. Desires position of responsibility with industrial concern, utility, consulting engr or teaching. B-7877.

### Inspection

ELEC. GRAD., 38, single, 6 yr experience factory testing, W.E. & M. Co., East Pittsburgh, Pa. One yr steel company installing and testing elec. equipment. 6 months' factory inspection of transformers. 2 1/2 yr general inspection of elec. equipment with insurance co. Good reference. Available immediately. Any location. D-1461.

### Instruction

GRAD. E.E., 7 yr teaching, 18 yr practical experience. The last 12 yr has been along mechanical lines; steam, gas, air and water engineering, [illegible] and alkali plants, handling, conveying, and process equipment. Taught heat power engineering at Oregon State College and elec. lab at Beaune, France. Location immaterial. A-3651.

GRAD. E.E., and M.S. in Physics, 30, married. Three yr teaching physics in univ. Five yr research, high voltage insulation studies; ferromagnetic alloys; a-c, d-c, high frequency measurements; high vacuum technique; X-ray analysis. Publications. At present grad. asst. in physics. Desires teaching physics or e.e. engg or research position. Available Jan. 1. D-1616.

## ENGINEERING SOCIETIES EMPLOYMENT SERVICE

57 Post St.
San Francisco

205 West Wacker Drive
Chicago

31 West 39th St.
New York

MAINTAINED by the national societies of civil, mining, mechanical, and electrical engineers, in cooperation with the Western Society of Engineers, Chicago, and the Engineers' Club of San Francisco: An inquiry addressed to any of the three offices will bring full information concerning the services of this bureau.

**Men Available.**—Brief announcements will be published without charge, repeated only upon specific request and after one month's interval. Names and records remain on file for three months, renewable upon request. Send announcements direct to Employment Service, 31 West 39th Street, New York, N. Y., to arrive not later than the fifteenth of the month.

**Opportunities.**—A weekly bulletin of engineering positions open is available to members of the cooperating societies at a subscription of $3 per quarter or $10 per annum, payable in advance.

**Voluntary Contributions.**—Members benefiting through this service are invited to assist in its furtherance by personal contributions made within 30 days after placement on the basis of 1.5 per cent of the first year's salary.

**Answers to Announcements.**—Address the key number indicated in each case and mail to the New York office, with an extra three-cent stamp enclosed for forwarding.

ASSOC. OR ASST. PROF. OF E.E., age 34, B.S. in E.E. and M.S. in E.E. degrees. Five yr teaching experience leading tech. school, 3 yr as asst. prof. Four yr in charge of education and training for national technical corp. Any location. C-8967.

**Junior Engineers**

M.S. in E.E. 1932, Univ. of Pa., 23, single, desires position affording e.e. experience. Salary secondary. Go anywhere. Available immediately. D-1601.

GRAD. E.E. 1929, M.S. in E.E. 1932; 18 months' test experience at G. E. Co. with all types of elec. machinery, also some research experience. Desires engg opportunity. Salary and location secondary. Available immediately. C-9003.

E.E. GRAD., 1932; Rensselaer P. I., Sigma Xi: 22; single. Desires work in any elec. field. Salary and location immaterial. Available at once. D-1296.

I.E.E. GRAD., Pratt Institute, 1932, 20, single. Specialized illumination. Completed Westinghouse illumination course. Capable and not afraid of hard work. Excellent references. Desires any kind of work in elec. field. Location immaterial. Available immediately. D-1594.

1932 GRAD. E.E., B.S., from So. Dakota Univ., 22, single and in excellent physical condition. Best of character standing and willing to work hard, starting at the bottom and working up. Desires any position that will pay living wage. Location immaterial and available immediately. D-1635-4393-Chicago.

E.E. GRAD., B.S. Carnegie Inst. of Tech. 1932. A.B. in mathematics Oberlin College 19[illegible]. Age 24, single, member of Eta Kappa Nu. Location and salary immaterial. Want to gain experience. Available at once. D-1640.

RECENT CORNELL GRAD., 23, single, holding B.S. in E.E. and M.S. deg.; desires connection with opportunity for a future responsible technical position. Excellent scholastic and personal records. A little factory experience. D-1621.

B.S. in E.E. 1931, Mich. Col. of Min. & Tech., single, 23, Tau Beta Pi. Desires work in any engg field. Experience: 3 months' swbd. wiring, 1 month lighting design, 6 months' surveying and map drawing. Speaks Finnish. Location in northern half of U.S. preferred. Available at once. D-1650.

YOUNG ENGR, 25, single. Brooklyn Poly. Inst. evening student, 1927 to date. Five yr varied experience, steam and elec RR construction, secretarial. Well versed in mathematics. Desires position in any engg field. Available immediately; location, New York City. C-8672.

B.S. in E.E. 1927. Married, 28. Five yr experience in telephone work. Desire engg work of any nature or position in law department of mfg. concern. Available immediately. D-1673.

E.E. GRAD., M.I.T., S.B., 1931, S.M. 1932, 2[illegible] single. 16 months' experience with Edison Electric Illuminating Co. of Boston as a cooperative student. Desires position in power transmission field, but is interested in any position with a reasonable chance for advancement. Location immaterial. References. D-1685.

GRAD. E.E., 1929, single, 24. Fifteen months' student engr on G. E. test. Some test, drafting and switchboard construction experience before graduation. Interested in position with concern doing consulting, or construction work or with utility or mfr. Available at once. Location anywhere in U.S., but New England preferred. C-8028.

B.S. in E.E. recent, 4 yr radio experience. Desires any position, moderate salary. Age, 22 years. D-1488.

B.S. in E.E., 1932, single, 21. Gained experience in elec. instrument plant during cooperative course. Desires any position for experience. Salary secondary. D-1578.

**Maintenance and Operation**

PRACTICAL ELEC. CONST. AND MAINT. CHIEF, age 32, single, 14 yr experience in construction work, also maintenance and operation of mines and industrial plants. Last 4 yr in Latin-America. Can speak Spanish and German well. Available immediately. Location, immaterial. C-2101.

ELEC. GRAD., 15 yr broad experience, factory testing, construction, substation operating and maintenance. Theoretical and practical. Desires position of responsibility. C-38.

**Research**

RESEARCH: testing and research engr: phys., tests of materials, metallography, X-ray and spectroscopic structure analysis. Well versed in physics. Languages: English, German, French. Location and salary of secondary importance to opportunities. C-6994.

M.S. in E.E., Johns Hopkins Univ., Univ. of Pa. fellowship holder, married, good health, analytical, 28. Two yr teaching experience, mathematics, physics, e.e., 2 yr practical, theoretical experience, long-distance telephone transmission from New York to San Francisco. Desires teaching, personnel, research along mathematical-physical lines, or invites correspondence. Excellent references. D-1609.

E.E., 28, married, has 3½ yr experience in lab., testing and research work, desires position, preferably with small concern anywhere in U.S. D-1657.

RESEARCH AND DEVMT. ENGR, B.S. and M.S. in E.E. Two yr additional grad. work in physics. Single, 28. Five yr with Westinghouse. Experimental work dealt with arc rupture, control apparatus, and the use of X-rays to study molecular structure. Location and salary secondary to position, with opportunity for future. D-1331.

HYDROLOGICAL & METEOROLOGICAL RESEARCH ENGR, B.S., M.S. & E.E., 7 yr hydroelec. experience in large public utility engg dept., 3 yr studying climate cycles, ground waters and storage reservoirs, forecasting precipitation runoff and storage, testing flow lines, penstocks and turbines, making stream measurements and snow surveys. Location U.S. or foreign. C-6853.

E.E. GRAD., Penn State, 1932, Honors, 22, single. Some experience in shortwave receivers. Desires research work in short-wave, ultra short-wave, photo electric cells, vacuum tubes, etc., also radio communication at sea. Either foreign or domestic field. Salary secondary. Available now. D-1513.

Sc.D. in E.E. M.I.T. '32; 7 yr Univ. education; 9 yr pract. exp., power, communication and business engg; 2 yr testing course; publications. Extensive knowledge of languages; available. Location immaterial. D-747.

**Sales**

SALES ENGR, 30, single, E.E. grad. of a reputable, one yr engg school. Five yr experience selling industrial and central station instruments. Desires position as salesman with a high grade mfg. concern. No particular line desired. Will travel, location immaterial. C-1570.

**Testing**

ELEC. INSPECTOR OR TEST MAN, 29, single, 8 yr experience with power and manufacturing companies. Also experience with automatic telephone equipment and communication. Knowledge of theory as well as practise. Can furnish best of references. Location immaterial. Available at once. D-1618.

# Membership

## Recommended for Transfer

The board of examiners, at its meeting of November 9, 1932, recommended the following members for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the acting national secretary.

**To Grade of Fellow**

Lyon, Waldo V., prof. of elec. machinery, Mass. Inst. of Tech., Cambridge, Mass.
Merwin, Louis T., vice-pres., and gen. mgr., Northwestern Elec. Co., Portland, Ore.
Sabbah, Hassan Camil Ali, elec. engr., Gen. Elec. Co., Schenectady, N. Y.
Sheehan, John E., chief engr., Houston Lighting & Power Co., Houston, Texas.

**To Grade of Member**

Adler, Wm. M., asst. to distribution engr., Bronx Gas & Elec. Co., Bronx, N. Y.
Beckman, Joseph S., engr. of plant extension, Bell Tel. Co. of Pa., Philadelphia, Pa.
Bricker, L. B., division maintenance supervisor, Southwestern Bell Tel. Co., Houston, Texas.
Bureau, E. A., prof. of elec. engg., Univ. of Kentucky, Lexington, Ky.
Burrows, C. R., radio research engr., Bell Tel. Labs., Inc., Deal, N. J.
Cannon, Robert S., pwr. plant foreman and elec. engr., Lago Petroleum Corp., Venezuela, S. A.
Gould, Leroy B., inductive relations engr., New England Tel. & Tel. Co., Boston, Mass.
Howarth, Oliver, technical engr. and meter supt., Lancashire Elec. Pwr. Co., Manchester, Eng.
Joh[illegible], Royce E., director, elec. stds. lab. and instructor in elec. engg., Univ. of Wisconsin, Madison, Wis.
Lidbury, Frank A., pres. and gen. mgr., Oldbury Electro-Chemical Co., Niagara Falls, N. Y.
Mueller, Walter E., patent solicitor, Denison & Thompson, Syracuse, N. Y.
Ortlieb, Otto P., engr. of street lighting, City of Trenton, Trenton, N. J.
Pokorny, Jerome J., elec. engr., Cleveland Elec. Ill. Co., Cleveland, Ohio.

## Applications for Election

Applications have been received at headquarters from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a grade higher than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the acting national secretary before Dec. 30, 1932.

Adams, E. F., 839 Monroe Ave., Elizabeth, N. J.
Anderson, I. Jr., 108 Burncoat St., Worcester, Mass.
Barbee, G. C., Southwestern Bell Tel. Co., St. Louis, Mo.
Barnett, H. G., Ore. State Col. Corvallis, Oregon.
Beale, F. S., 1802 Cleveland Blvd., Caldwell Idaho.
Beard, W. G., Rippowam, Ridgefield, Conn.
Beckert, J. E., 27 Clarendon Place, Buffalo, N. Y.
Bell, J. S., Mass. Inst. of Tech., Cambridge, Mass.
Brainard, W. E., 12222 Taft Ave., Cleveland, Ohio.
Briansky, D., 6730 13th Ave., Brooklyn, N. Y.
Brigham, E. R., 1503 Superior St., Toledo, Ohio.
Brown, J. D., Hatfield Wire & Cable Co., Hillside, N. J.
Bruggink, C. P., 309 10th St., Hoboken, N. J.
Burmiester, H., Safe Harbor Water Power Corp., Safe Harbor, Pa.
Calkins, D. S., Henrietta, N. Y.
Carlson, R. W., No. Dak. R. R. Commission, Bismarck, N. D.
Carson, H. E., New England Power Engg & Service Corp., Worcester, Mass.
Colegrove, W. D., Remus, Mich.
Collins, J. E., National District Telegraph Co., New York, N. Y.
Crawford, E. J., Oyama, B. C., Canada.
Deck, H. A., Gen. Elec. X-Ray Corp., Dallas, Texas.
Devine, B. A., City & County of San Francisco, Calif.
Frey, G. O., Warner Bros. Theatres, Inc., New York, N. Y.
Gammons, J. M., Southwestern Bell Tel. Co., St. Louis, Mo.
Gegely[illegible], C., United Electric Lt. & Pwr. Co., New York, N. Y.
Gerlach, W. G., Gen. Elec. Co., Toledo, Ohio.
Gustafson, W. G., Bell Tel. Labs., Inc., New York, N. Y.
Hagood, G. B., Jr., Winnsboro, S. C.
Hanson, J. W. (Member), Columbia Engg. & Mgt. Corp., Cincinnati, Ohio.
Harvey, G. C., Gibbs & Hill, Inc., Rahway, N. J.
Hatfield, L. N., KWSC, State Col. of Wash., Pullman, Wash.
Haward, R., The Saskatchewan Pwr. Commission, Regina, Saskatchewan, Can.
Hawley, E. F., Ormstown, P. Q., Canada.
Heidenreich, E. C., Dental & Medical Elec. Equipment, Buffalo, N. Y.
Hope, H. W., 338 Harvard St., Cambridge, Mass.
Howell, W. J., Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
Hudgins, W. D., 1422 Arch St., Berkeley, Calif.
Hutchinson, M. C., 316 West 14th St., New York, N. Y.
Johnson, H. W., 31 Washington St., East Orange, N. J.
Johnson, V. T., 3610 Bellevue Ave., Los Angeles, Calif.
Juc[illegible]arone, N. T., Otis Elevator Co., Yonkers, N. Y.
Kahlbaum, M. E., Kahlbaum Brothers, Carleton, Mich.
Kastens, R. H. C., 105 Hauxhurst Ave., Weehawken, N. J.
Kelsay, W. D., 401 Martinique St., Dallas, Texas.
Kowalewski, H. M., B. F. Sturtevant Co., Boston, Mass.
Kuhlman, P. W., 509 Smith Ave., Detroit, Mich.
Laine, M. W., 546—40th St., Brooklyn, N. Y.
Libby, C. C., University of Cincinnati, Cinc., Ohio.

Lindsay, V. H., B. F. Sturtevant Co., Hyde Park, Mass.
Lindsley, R. P. Jr., So. Methodist Univ., Dallas, Texas.
Lockie, A. McL., Rensselaer Polytechnic Inst., Troy, N. Y.
Mahalak, A. F., Michigan Alkali Co., Wyandotte, Mich.
Malone, C., Jr., Monongahela West Penn Public Service Co., Fairmont, W. Va.
Martinson, E. O., Box 5, Harrah, Wash.
McCracken, G. I., 152[illegible] Termon Ave., N. S., Pittsburgh, Pa.
McFarlin, V. S., 922 Beacon St., Boston, Mass.
McNarney, H. J., 158 West Maple St., Wabash, Indiana.
Miller, H. W. R., New York Tel. Co., New York, N. Y.
Miller, W. H., 1956 North High St., Columbus, O.
Mitchell, F. H., Mitchell Radioservice Co., Mobile, Ala.
Morgan, J. M., 737 Ridgway Ave., Morgantown, W. Va.
Morton, P. L., Firland, Richmond Highlands, Wash.
Mowat, D., Saskatchewan Power Commission, Regina, Saskatchewan, Can.
Munroe, J. P., 120 Hobart St., Ridgefield Park. N. J.
Osgood, V. L. (Member), Hardwick-Hindle, Inc., Newark, N. J.
Parsons, C. B., 1261 Atlantic St., Portland, Oregon.
Pashek, R. J., 1969—25th St., Detroit, Michigan.
Rahlke, H. W., P. O. Box 199, Salem, Ohio.
Ranson, L. R., Gen. Elec. Co., Schenectady, N. Y.
Reizenstein, M., Jr., 2134 Brookfield Ave., Baltimore, Md.
Riedy, K. F. R., Route No. 4, Allentown, Pa.
Roberts, F. F., R. F. D. No. 2, Parma, Idaho.
Rogers, A. G., Clio, Mich.
Roswell, E. R., P. O. Box 203, Devon, Conn.
Scrutchin, C. G., 227 Hancock St., Decatur, Ga.
Sechler, F. E., Great Western Sugar Co., Ovid, Colo.
Sann, J. W., Southern Bell Tel. & Tel. Co., Louisville, Ky.
Stanton, S. W., United Electric Lt. & Pwr. Co., New York, N. Y.
Sterling, O. R., Hop Bottom, Pa.
Stewart, H. M., Humble Oil & Refining Co., Baytown, Texas.
Stieg, H. R., 157 Monroe St., Hartford, Conn.
Tankovich, J. G., 497 East 11th Ave., Columbus, Ohio.
Thomas, R. G., Carolina Pwr. & Lt. Co., Raleigh, N. C.
Walsh, W. C., Rt. No. 2, Box 379, Gilroy, Calif.
Wanger, L. R., Phila. Elec. Co., Philadelphia, Pa.
Wiedenheft, A. H., Good Thunder, Minn.
Willson, W. H., Jr., Randall, Iowa.
Wells, M. F., 261 Hartford Ave., Wethersfield, Conn.
West, C. V., 2001 Barton Ave., Richmond, Va.
Weston, F. B., Sage Allen & Co., Inc., Hartford, Conn.
Womack, S. H. J., Bureau of Standards, Washington, D. C.
Woodruff, R. T., 232 E. Broadway, Girard, Ohio.
Woodward, M. W., Cheyenne Wells, Colorado.
Young, C. E., Johns Hopkins Univ., Baltimore, Md.
Zeitz, A., 264 Berriman St., Brooklyn, N. Y.
95 Domestic

### Foreign

Lautier, V., 37 Sda. San Paolo, Cospicua, Malta.
Lindorf, L. S., Bol. Kommunisticheskaia 7 Kv. 1 Moscow 4, U.S.S.R.
Lloyd, H. S., Metropolitan-Vickers Elec. Co. Ltd., Traford Park, Manchester, England.
Sarda, P. M., Ratan Pole, Nagori Pole, Ahmedabad, India.
Singh, H., Simla Municipal Committee, Idgah, Simla, India.
Swami, T. V., Elec. Dept., Cocanada, India.

# Engineering Literature

Unless otherwise specified, books in this list have been presented by the publishers. The society does not assume responsibility for any statement made; these are taken from the preface or the text of the book.

All books listed may be consulted in the Engineering Societies Library.

BERECHNUNG von GLEICHSTROM-KRAFTÜBERTRAGUNGEN. By O. Burger. Berlin, Julius Springer, 1932. 82 p., illus., 9x6 in., paper, 6.40 rm.—A practical discussion of the calculation of long-distance a-c transmission lines, in which attention is paid to economic and electrical factors. Various methods of transmission are compared.

COMPANY PLANS FOR UNEMPLOYMENT RESERVES. Washington, D. C., Chamber of Commerce of the U.S., Dept. of Manufacture, 1932. 42 p., tables, 9x6 in., paper, gratis.—To assist employers who desire to devise means for protecting their staffs from unemployment. Purpose and advantages of company reserve plans, coverage and experience of existing plans, procedures for establishing plans, and development of uniform plans by industries or communities, are discussed.

ELECTRIC AND MAGNETIC FIELDS. By S. S. Attwood. N. Y., John Wiley & Sons, 1932. 314 p., illus., 9x6 in., cloth, $3.50.—Represents a course given to students of E.E. at the Univ. of Mich., to coordinate the under-class work in mathematics, mechanics and physics with professional work of the last 2 years. The book is in 4 parts: electric field; magnetic field; ferromagnetic field; and combined electric and magnetic fields.

ELECTRONS AND WAVES. By H. S. Allen. Lond. & N. Y., Macmillan Co., 1932. 33[illegible] p., illus., 8x5 in., cloth, $2.50. Consists of lectures dealing with recent progress in our knowledge of the constitution of matter and the nature of radiation. Intended for readers who have not specialized in physics, but who wish something more than an entirely elementary account of the subject. Such topics as relativity, the quantum theory, radioactivity and wave mechanics are presented in this concise outline.

ELEKTRISCHE GASENTLADUNGEN. Bd. 1. By A. v. Engel and M. Steenbeck. Berlin, J. Springer, 1932. 248 p., illus., 10x6 in., cloth, $5.50 rm.—This treatise, which will comprise 2 volumes, aims to provide a systematic, comprehensive discussion of the discharge of electricity through gases, in which the needs of the experimenting physicist and the research engineer will be given consideration above those of the student of atomic physics. This volume develops the basic laws of discharges in gases from simple concepts, without using difficult mathematical processes and compares them with experimental results.

HANDBOOK of CHEMISTRY and PHYSICS. Edit. by C. D. Hodgman. 17 ed. Cleveland, Ohio, Chemical Rubber Pub. Co., 1932. 1,722 p., tables, 7x5 in., leather, $6.00.—This edition has undergone an extensive revision which has resulted in an addition of 150 pages of new matter. 1,000 new compounds have been added to the table of physical constants of organic compounds, which now includes over 4,000 substances, and the former data carefully corrected. The mathematical section has been enlarged by adding several useful tables; new tables have been added to all divisions of the book.

HANDBOOK of INDUSTRIAL TEMPERATURE and HUMIDITY MEASUREMENT and CONTROL. (Manual of Instrumentation.) Parts 2 and 3. By M. F. Béhar. Ed. 1. Pittsburgh, Instruments Pub. Co., 1932. 309 p., illus., 10x6 in., cloth, $4.00.—Having presented the fundamentals of industrial instrumentation in his first volume, Mr. Béhar now takes up 2 subjects, the measurement and control of temperature and of humidity. Detailed information is presented upon thermometers, pyrometers, heat recorders and controllers, and instruments for measuring and controlling humidity. Detailed descriptions of the principal instruments on the market, and general principles underlying them are presented.

Die KÜNSTLICHEN KOHLEN für elektrische Öfen, Elektrolyse und Elektrotechnik. By K. Arndt. 2 Auflage. Berlin, J. Springer, 1932, 336 p., illus., 9x6 in., leather, 38 rm.—A comprehensive account of the carbon electrode industry. After a short historical introduction, raw materials are considered, their mixing, ignition and preparation described. Chapters then follow upon chemical, physical, and microscopic testing and upon the use of carbon electrodes in furnaces and baths. Carbons for arc lamps, brushes, batteries, microphones, and other purposes are discussed. The book is a rewritten edition of Zellner's work on this subject.

REFRIGERATION, including Air Conditioning and Cooling and Household Automatic Refrigerating Machines. By J. A. Moyer and R. U. Fittz. 2 ed. New York and London, McGraw-Hill, 1932. 538 p., illus., 9x6 in., $5.00. Intended both as a textbook and reference work as a useful outline of current conditions and practise. The theory of refrigeration and the methods in use are described and explained. New features of improved designs of household and small commercial refrigerators, silica-gel systems, revised data on refrigerants, production of dry ice, applications of quick freezing, and air conditioning, are described.

REWINDING SMALL MOTORS. By D. H. Braymer and A. C. Roe. 2 ed. New York & London, McGraw-Hill, 1932. 263 p., illus., 9x6 in., cloth, $2.50. Intended as a guide to repairmen called upon to rewind portable drills, motors for automobile starters, sewing machines, vacuum cleaners, fans and other small machinery. A chapter on single-phase motors of the condenser type has been added. The directions are full and detailed and sufficient for all needs of experienced winders.

STEAM POWER PLANT ENGINEERING. By L. A. Harding. New York, John Wiley & Sons, 1932. 777 p., illus., 9x7 in., cloth, $10.00. To outline briefly in an elementary manner the major problems in the design of steam generators, engines, turbines and accessories, to show their interrelations in power plant engineering, and to discuss the economic factors involved in their selection. A large amount of practical data not readily accessible elsewhere is assembled in convenient form, making it useful for reference as well as for study.

TABLES OF CUBIC CRYSTAL STRUCTURE OF ELEMENTS AND COMPOUNDS. By I. E. Knaggs, B. Karlik and C. [illegible]. Elam. London, Adam Hilger, Ltd., 1932. 90 p., tables, 10x6 in., cloth, 11s. 6d. A useful reference book for chemists and metallurgists who use X-ray methods for the analysis of powders and crystals. One section upon inorganic and organic substances; and another upon alloys. Each section gives table listing the substances: alphabetically, and systematically by the side length of the unit cube cell. The bibliographies contain over 900 references. An attempt to tabulate all data scattered through periodicals up to August 1931.

THERMODYNAMICS. By J. E. Emswiler. New York & London, McGraw-Hill, 1932. 347 p., 9x6 in., cloth, $3.00. The special feature of this textbook is a progression from the topics most familiar to the student to those with which he is inexperienced. Study of the steam engine comes first, followed by vapor refrigeration, permanent gas mixtures and air heat engines; finally the laws of thermodynamics and the kinetic theory of heat. Earlier edition partly rewritten and new matter added.

URBAN LAND USES, Amounts of Land Used and Needed for Various Purposes by Typical American Cities, an Aid to Scientific Zoning Practice. (Harvard City Planning Studies, v. 4.) By H. Bartholomew. Cambridge, Harvard Univ. Press, 1932. 174 p., 10x7 in., cloth, $3.50. The results of an investigation undertaken to determine the requirements of the American city as to the land areas used for various purposes, the ratios of these areas to a given population unit, and analogous statistical information of aid in scientific zoning. These data provide a method for estimating the total area required for each particular urban use for any given future population of between 5,000 and 300,000 inhabitants.

WORLD SOCIAL ECONOMIC PLANNING, the Necessity for Planned Adjustment of Productive Capacity and Standards of Living. 2 v. The Hague, Holland, Intl. Industrial Relations Inst., also Room 600, 130 East 22nd St., New York, 1932. 935 p., 10x6 in., cloth, $2.50. Containing papers and discussions presented at the Congress in Amsterdam in 1931, where the necessity for planned adjustment of productive capacity and standards of living was discussed by a group of economists and sociologists of many countries.

**Engineering Societies Library**

**29 West 39th Street, New York, N.Y.**

MAINTAINED as a public reference library of engineering and the allied sciences, this library is a cooperative activity of the national societies of civil, electrical, mechanical, and mining engineers.

Resources of the library are available also to those unable to visit it in person. Lists of references, copies or translation of articles, and similar assistance may be obtained upon written application, subject only to charges sufficient to cover the cost of the work required.

A collection of modern technical books is available to any member residing in North America at a rental rate of five cents per day per volume, plus transportation charges.

Many other services are obtainable, and an inquiry to the director of the library will bring information concerning them.

## Industrial Notes

**General Electric to Exhibit at Chicago Fair.**—The "House of Magic," a spectacular section of the G-E research laboratories, will be moved to Chicago for the 1933 World's Fair as the outstanding feature of the General Electric Company's exhibit. The exhibit will occupy 9,000 sq ft of space in the circular hall of the Electrical Building and will represent an investment of five hundred thousand dollars.

**Roller-Smith Appointments.**—Mark G. Mueller, 1700–16th St., Denver, has been appointed by The Roller-Smith Co., New York, as district sales agent for the states of Colorado, New Mexico, and the western part of Kansas. Burkholder and Kelley, 105 Cortleigh Boulevard, Toronto, have been appointed representatives for the Dominion of Canada.

**Rockbestos Moves Chicago Office.**—The Rockbestos Products Corp., New Haven, Conn., manufacturers of asbestos insulated wires and cables and flexible cords, announces a change in the location of its Chicago office and warehouse from the Madison Terminal Building to the Marquette Building, 140 So. Dearborn St., Chicago, Ill.

**L. M. Christie Promoted by National Fireproofing Corporation.**—L. M. Christie has been elected vice-president of the National Fireproofing Corporation, Pittsburgh, with which he has been connected since 1902. He will continue in charge of the sales engineering end of the conduit division. Mr. Christie has been identified with the clay conduit branch of the electrical industry almost from its inception, coming to the states from Windsor, Canada, in 1900 to enter the employ of John T. McR[illegible]. The latter was an inventor and a pioneer manufacturer of the present type of multiple duct clay conduit for housing telephone, telegraph, and electric power cable lines.

**Calculating Board in Regular Use by Utility.**—Studies of power flow, regulation, losses, power factor and system stability are made quickly and easily on the alternating-current calculating board recently installed in the engineering department of the Commonwealth Edison Company, Chicago. Built by the Westinghouse Electric & Manufacturing Company, it is said to be the first alternating-current calculating board to be placed in regular use by an operating utility. It operates on a frequency of 440 cycles. On it can be reproduced in terms of circuit constants the whole or any part of the Commonwealth Edison a-c system.

**General Electric Receives Largest Mercury Shipment.**—What is probably the largest single shipment of mercury ever made arrived in New York recently for the General Electric Company, to be used in generating power in the new 20,000-kilowatt mercury turbine just installed at the Kearny station of the Public Service Corporation of New Jersey. The shipment consisted of 270,000 pounds, and was delivered in 3553 iron flasks, each flask containing 76 pounds. The value of the mercury in the whole order is about $350,000, as this shipment represents only half of the company's needs. The remaining 270,000 pounds will be delivered later and will be used for generating power in the new mercury turbine plant being built in Schenectady. The total order represents about 89 per cent of the mercury consumed by the United States in an average year.

**Bristol Opens British Factory.**—The Bristol Co., Waterbury, Conn., announces the establishment of a British factory at London under the name of Bristol's Instrument Co., Ltd. Since 1889 the Bristol Company has had a very substantial trade with Great Britain in its line of recording instruments, its selling activities in that country being handled by J. W. & C. J. Phillips, Ltd., as sales agent. Although the general expansion program of the company contemplated the founding of a British plant at some future time, the altered economic and business situation within Great Britain made an earlier establishment for manufacturing in that country seem advisable. Howard H. Bristol, president of The Bristol Company, recently made a special trip to London to investigate the situation, and during his visit laid the plans and arranged for the formation of the British company. The new plant, located at 144 Pomeroy St., New Cross, London, consists of an office building and a two-story factory building of modern construction, and is prepared to manufacture and service the complete line of the company's indicating, recording and controlling instruments.

**A New Testing Device.**—Ferranti, Inc., New York, has introduced a complete testing kit comprised of the dual range clip-on ammeter, which met with widespread acceptance a few months ago, and a three range portable voltmeter. The clip-on ammeter has two scales, 0/100 and 0/500 amperes, and reads accurately currents ranging from 10 to [illegible] amperes without the necessity of breaking the circuit or the use of split-core current transformers. The instrument is simply clipped over the conductor and the current is read off directly. It can be operated with one hand, and is suitable for use either on the ground or up a pole. The second instrument in the set, the triple range portable voltmeter, has full scales of 150, 300, and 600 volts which take care of the standard distribution voltages of 110, 220, 440, and 550. This meter, although of the moving iron type, has a comparatively high resistance, making its readings extremely accurate. It is suitable for use on either direct or alternating current and is independent of frequency between 25 and 100 cycles.

The two instruments in this set are accurate and convenient, and although of a precision nature, they are robust in construction. They are supplied in a solid leather case equipped with lock and key, in addition to hand and shoulder carrying straps. The set is particularly adapted for determining the actual voltage and loading on transformers, motors, etc., for balancing secondary transformer loads on three-wire services, or for checking power consumers' loads and voltages. It may also be used to check single or three-phase kva.

## Trade Literature

**Arc Welders.**—Bulletin HW-2, 20 pp. Describes the improved line of P & H Hansen arc welders, designed by K. L. Hansen. Harnischfeger Corp., Milwaukee.

**Condensers.**—Catalog, 16 pp. Included in this complete line are a series of oil impregnated, oil filled paper condensers especially adapted for use with capacitor motors, power factor correction and other industrial applications. Electrolytic, paper and mica condensers are also described. Dubilier Condenser Corp., 4377 Bronx Blvd., New York.

**Wire Rope Slings.**—Catalog, 86 pp. Includes the latest available information on various types of slings now being used in shop and field for the handling of all kinds of loads. Numerous illustrations show the application of these slings in handling heavy apparatus and castings. John A. Roebling's Sons Co., Trenton, N. J.

**Square Case Instruments.**—Bulletin L 20545, 8 pp. Describes a new line of switchboard square-case instruments, including ammeters, milliameters, voltmeters, milli-voltmeters, single and polyphase power factor meters, frequency meters, and synchroscopes. Both a-c and d-c instruments are intended for service on large switchboards of steel, ebony asbestos, or slate. Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

**Zinc for Die Castings.**—Bulletin 20 pp. Illustrates a multiplicity of uses for zinc die castings. Charts and table on the effect of aging treatments on tensile strength, impact strength, and dimensions of the "Zamak" alloys are published for the first time. Heat treatment for stabilizing the dimensions and properties of a zinc die casting alloy is also discussed. New Jersey Zinc Co., 160 Front St., New York.

**Metal-Clad Switchgear.**—Bulletin GEA 1661, 12 pp. Describes type MI-6, latest G-E metal-clad switchgear, for a wide range of applications—central station main and auxiliary circuits, industrial plants, etc. The principal improvement of many in this apparatus is the use of oil-blast circuit breakers having interrupting ratings from 50,000 to 500,000 kva, 15,000 volts and up to 2,000 amperes. Each unit consists of a complete self-contained switching equipment with a stationary and removable element. General Electric Co., Schenectady, N. Y.
